CHRYSANTHEMUM culture both outdoors and under glass is seriously menaced by the European corn borer. The spread of this destructive pest is somewhat slow, but steady. Like some other dangerous pests it was introduced not on live plants; in fact, the powers that be can merely guess as to how it landed here. In addition to working on corn, it has this season destroyed much of the celery produced for the Boston market, and dahlias, gladioli, zinnias, asters, and one or two other garden favorites are commonly attacked. One chrysanthemum grower in Arlington, Mass., lost \$7,000 worth of flowers this season, and the end is not yet. What with the midge, thrip, aphid, leaf miner and sundry other pests and diseases, the Queen of Autumn has its share of foes. A point to remember about the corn borer is, that it thrives on numerous weeds; in fact, it has been found on at least two hundred different plants, and the burning up of stubble and all dry refuse matter is one of the best ways of preventing its spread.

I was pleased a few days ago to come across a batch of that one-time popular flower, *Thysanacanthus rutilans*, now called *T. Schombergkianum*. No doubt many of our readers will remember this bright and pretty Winter flowering plant, a native of Colombia, which is of shrubby habit and produces great numbers of long racemes, the flowers on which are tubular, scarlet in color and pendulous. I cannot but think that on private estates some of these might well be seen in addition to such plants as *Centradenias*, *Libonias*, *Sericographis* (or *Jacobinias*), *Linums*, *Goldfussia* (*Strobilanthes*), *isophyllus*, and others which might be named. Not long ago hardwooded plants were in but a few hands; we see a steady increase in the culture of camellias on private estates while ericas, *Daphne indica*, and others are all coming back into favor. Of course, those of us who live near the seaboard or in the uplands where Summer's torridity is tempered can grow these better than our friends further inland, but experience has clearly shown that there is a much larger area than imagined where hard wood succeeds, and I look to see a coming back into favor of some of the softer-wooded subjects named also.

This has been a great year for dahlias; never did they bloom more abundantly or longer. The number of varieties is absolutely bewildering and senseless, and those catalogue men who have the courage to prune their collection of the various types to a dozen varieties each are

to be commended. The craze for mammoth flowers persists. Personally, I fail to see much decorative value in these monsters. In nearly every case these big varieties look better cut than on the plants; in fact, many of them cannot be seen *at all* on the plants. What we need more than anything else is a strain of dwarf or medium height which will throw flowers well above the foliage. Give us plants of such a strain as this, and it will be of some value in the flower garden. At the same time, reduce the size of the flowers. At present we have really no dahlia adaptable for culture in either a formal or natural garden, the singles and cactus come nearest to filling the bill. It looks as if there might be considerable food value in the roots, and if present experiments of the government prove encouraging, we may see big dahlia areas planted for this purpose in the not distant future. But in the meantime, call a halt on the big flowers, and give us something with more grace and beauty.

Some thirty years ago when we were growing such old-time carnations as *Anne Webb*, *Astoria*, *Ferdinand Mangold*, *Portia*, *Grace Wilder* and *Hinzes White*, I was much troubled with cutworms outdoors, and, after resorting to hand picking and various sprays, I at last concluded to try a dressing of gas lime amongst the plants which stopped the work of destruction in short order, and to any who are badly troubled with this and other soil pests, I would say, apply a dressing of this gas lime now, and if the soil remains open, work it in with a cultivator or rake. You will not only make the soil obnoxious for cutworms, the destructive white grub which is the larva of the May beetle and other pests, but there is no better remedy for club root on members of the *Brassica* family. The gas companies will usually give you the lime for the hauling, and if the patch to be treated covers, say, half an acre, use fifteen hundred or two thousand pounds of the gas lime. Try it and be convinced.

Celery blight has been unusually rife this season, and both private gardeners and commercial growers have sustained heavy losses. Those who persisted in the use of home-made Bordeaux Mixture, five pounds of copper sulphate and five pounds of lime to fifty-four gallons of water and sprayed weekly had little disease. Those who neglected to do this, lost a large proportion of their crop. Celery is such an important garden vegetable that it is worthy of a little extra effort to keep it healthy. There is less and less celery each season kept outdoors on private

estates, now that labor is scarce and high. It entails a great deal of extra labor to bank up, protect, and dig celery in the open. In a warm Winter, it is likely to sweat and rot; mice and rats will gnaw at it if there is not a good frozen crust of earth protecting it beneath the mulch. If we have an early Spring, it will spoil much more quickly than celery well packed in a good cold cellar.

* * *

For forcing under glass, what is the best head lettuce? This is a question often asked. Boston is a great center for lettuce culture under glass, many acres being devoted to it. Practically three varieties only are grown today, viz., May King, Hittinger's Belmont, and French Unrivalled. Personally, I like the last-named best of all. The difficulty with May King is that, while it heads beautifully, it is very likely to burn at the edges when headed up, if a very clear sunny day follows several dark days. May King, however, is still grown more than any other sort. Golden Queen, one of Sutton's varieties, I believe, of a pale color, has given good results. We customarily think of lettuces as somewhat shallow rooting vegetables and that twelve inches is a fair depth for roots to go down. Mr. Hittinger of Belmont, a noted lettuce specialist, told me several years ago that having occasion to cut a drain across one of his mammoth lettuce houses, he found lettuce roots four and a quarter feet long, and he believed that they would have gone even deeper had soil conditions permitted.

* * *

At our Summer and Fall exhibitions we frequently find classes for collections of vegetables arranged for effect, and the group at the Museum of Natural History Show in New York last month from James McCarthy was undoubtedly the finest single exhibit at that excellent show. How rarely do we see a class provided now-a-days for a collection, say, of twelve varieties of fruits arranged for effect with suitable decorative material? Surely we have ample material for such a class in greenhouse and open air grapes, peaches, plums, nectarines, figs, apples, pears, Autumn fruiting strawberries and raspberries. The Massachusetts Horticultural Society has added such a collection class for a great vegetable and fruit show to be held on September 28-30, 1923. Cannot other societies be induced to do likewise? Properly staged collections of fruits, such as are seen at the great English shows, are always stunning features, and we should easily be able to duplicate them here with our greater fruit facilities.

* * *

The November exhibition of the Rhode Island Horticultural Society, combined with a number of other kindred bodies, held in the state armory, Providence, November 17-20, brought out one of the grandest fruit displays I have seen in a long time. Various associations and fruit firms put up large and very comprehensive displays which were arranged most artistically, with all exhibits named and the country of origin marked in addition. Over 100,000 people viewed the exhibition, and the wonderful fruit collections far outclassed the floral exhibits in interest for the general public. Surely one or two honorary displays of this kind should add interest to any of our Autumn exhibitions. In one collection, I noted fruits from California, Florida, Oregon, Canada, the eastern States, Hawaii, Jamaica, Honduras, Italy, England, Belgium, France, Jaffa, Spain and Porto Rico. It would be hard to find an individual who would not enthuse over such a varied fruit collection as this.

* * *

When we look back a few years, it is surprising to note the advance in popularity of annuals for greenhouse culture. Sweet peas are probably the best known and the

most largely grown annual for forcing, while calendulas, mignonette, godetias, Clarkias, bachelor's buttons, sweet sultans, lupines, larkspurs, and many more also are grown. Nemesias have become extremely popular, and justly so. There are few annuals which cannot be cultivated successfully indoors, and our commercial friends make use of stocks, candytuft, and *Gypsophila elegans* for Memorial Day trade. A variety which makes a good pot plant and can be flowered by making successive sowings from November until June, is *Statice Soworowe*. A friend who made a sowing late in the Summer, planted a couple of benches with it, and these will be in bloom for Christmas. This pretty lavender-pink colored everlasting makes a pleasant addition to the not too varied list of available flowers for the holidays.

* * *

It has been a wonderfully clear and open Fall, very favorable for many who have but a limited fuel supply on hand. We may get severe snow and ice storms at any time, and all true garden lovers fail to do their full duty if in such times they do not feed our best friends, the birds. Pieces of suet or fatty meats, securely fastened to trees are much appreciated by many, and may save some valuable little lives. Bread crumbs, scraps of meat, or small mixed grains, with some grit added, will also be enjoyed, and it will not be so much labor to clear a piece of ground of snow and give our feathered friends a daily repast. We are well rewarded for any little efforts and expense by watching the pleasure of the twittering birds, and later on they will repay us many fold for helping them.

* * *

Our evergreens are now coming in for their annual mutilation. I am not referring to those on private estates which can be classed as reasonably safe from vandals, but take a walk or drive on any pleasant Sunday in December, and note how many automobiles are carrying their loads of spruce, cedar, mountain laurel, pine, or other conifers. The desire for Christmas decoration is natural and commendatory, but the increasing depredations of auto vandals in our woodlands and fields is a scandal. Too bad that these, in common with other law-breakers, could not have a taste of the old cat-o'-nine-tails. It is only the nice, shapely cedars, pines, or spruces which are cut for Christmas trees. The ill-shaped ones are left to grow up for timber. With forest areas gradually diminishing, something must be done to curb and regulate this traffic. It is a pleasure to note that many churches and individuals refuse to buy any mountain laurel, and that some retail florists refuse to sell it. May their numbers steadily increase!

* * *

How lovely it is these Winter days when snow mantles Mother Earth, to stroll in our northern woodlands! Some there are who fail to note the beauty which everywhere abounds, and who think that a greenhouse is the only place for the gardener in such weather. Greenhouses are interesting and pleasurable, and we need more of them, especially small ones for suburban homes such as we find so abundantly abroad. But why compare the floral beauties of the greenhouse subjects with the more truly majestic ones of our great outdoors? The man or woman who cannot see beauty, symmetry, strength, and vigor in the glorious American elms, maples, oaks, pines or birches, silhouetted against the sky, or cannot admire the great variations in bark colorings of many shrubs and trees is no true gardener and is to be pitied. We hear of many Spring, Summer, and Autumn field days, but how few there are in Winter! Personally, I see great

(Continued on page 334)

Combinations of Flowering Plants

ALLISON M. WOODMAN

MANY flowers—and I use this term advisedly, meaning the flower to be a combination of the plant and blossom—are attractive enough in groupings of the same variety or of several varieties of the same species, but some of the best effects are obtained when several species of flowers, frequently, quite different in appear-

Snapdragons can be planted freely in amongst Petunias (on the left). Pansies (center) are excellent for planting in the panel in the center of the garage drive, while Shasta Daisies make a splendid border plant.

ance, but having harmonious colors and fine texture of foliage, are placed in the same group.

A blaze of one vivid color is quite effective in flower beds located in large parks and extensive estates, but on small places it is in better taste to use flowers with soft tones that blend. White is a good intermediate color to use, often effecting a transition between two violent, contrasting colors. People are subject to decided temperamental tastes in grouping flowers. One person will demand the grouping of vivid reds and blues; another will show a preference for some other strongly contrasting colors. Many show an utter lack of sense in color values.

Nature seldom makes a mistake in her selection of colors within the same flower. There is a gradual gradation between colors, or, if distinct, they contrast well. Therefore, it seems quite useless to continually harp on the subject of selecting flowers solely for color combinations. Flowers with pronounced colors like orange, yellow, and brown, should usually be planted separate from other flowers. Flowers like Zinnias and Salpiglossis with vivid, bizarre colors had best be planted in separate beds, although flowers of similar character occasionally strike a special note in groupings.

A bed of Scarlet Salvias is a distinct novelty and is very striking if rightly located, but to avoid too glaring an effect, needs to be relieved by a background of lark green foliage. A few inserted here and there in the flower bed to supply a contrasting color creates a much more pleasing and less obnoxious effect than a single bed of Salvias conspicuously placed in the center of a lawn.

There are many kinds of flowers with "mixed" colors giving pleasing combinations when certain colors are eliminated. In a mixed planting of Snapdragons (*Antirrhinums*), for instance, bright yellows should be eliminated; flowers with delicate shades of pink, or with pink gradating to white, make good combinations. There is

considerable difference of opinion as to the merits of single or mixed colors in beds. The best seed companies make a practice of sending out only the best colors in mixed lots of seeds. A bed of mixed colors is not apt to be so monotonous as a bed containing flowers of one color. However, where there is sufficient room, a flower of one color often makes a very striking effect.

Foliage is very important to consider in grouping together certain kinds of flowers. Frequently, too little thought is given to character of foliage, and yet this is the one factor which prohibits the grouping of some flowers. Flowers with coarse foliage, like Dahlias, should either be placed in groups by themselves, or in the background of flower borders. Flowers with finely divided foliage usually have splendid grouping qualities. Dark green is to be preferred to yellow-green foliage.

Every type of flower has its own series of colors running through several or many varieties, which cannot be duplicated in any other type. It is amazing to consider the hundreds of different color tones to be found in flowers. Color and form are dominant over size in relative importance, with fragrance constituting a very desirable factor. In the most attractive flower form, color, and fragrance reach perfection in the same bloom.

Time of blooming is another important consideration. Considerable has been written on the subject, and, while planting tables are important, they cannot always be ab-

A fine example of naturalistic planting. The White Marguerite is a good intermediate plant to use between groups of flowers which might not harmonize in color.

solutely relied upon. Flowers follow certain seasons in their blooming periods, but there is no assurance just when they will bloom during the season. It is unreasonable to expect flowers to bloom out of season, but it is possible, by making successive sowings of seeds, to get some flowers to give successions of bloom. Cutting off old blooms is a great aid in extending the blooming period. Late Spring, early Summer, and early Fall are the three periods of the year when seasonal flowers are apt to be in bloom simultaneously.

The period of simultaneous blooming will usually be brief in duration, but it is quite possible that there will be an overlapping of bloom. Some flowers have a long blooming period anyway, and it is well for the beginner to use such flowers to form the nucleus of the flower bed. As a last expedient, it is advised that the gardener "take a chance" and experiment with different kinds of flowers, studying local conditions of soil and climate, until interesting combinations of flowers have been worked out. In

An Attractive Combination of Canterbury Bells, Sweet Williams and Dianthus.

my own experience I have discovered that gardening is somewhat of a lottery—combinations entirely satisfactory one season are disappointing the next. And strange to say, some of the most effective combinations have been brought about entirely by accident. There are such variations in soil and climate throughout the country, that what applies to one locality will not apply to another—which recalls the old injunction: "Work out your own salvation."

Flowers with soft tones blend together very well. A beautiful combination consists of Canterbury Bells (*Campanula media*), or the less coarse Peach Bell (*C. persicifolia*), in the background, and then in order, Sweet William, *Phlox drummondii*, with Pinks (*Dianthus*) for a border plant. Perennial Phlox and Tall Snapdragon, using similar colors, make a fine combination, both flowers coming into bloom about the same time.

When the perennial border is mentioned one naturally thinks of a border filled entirely with perennials, but it can be made more interesting by the addition of a few annuals, which serve to fill up gaps during blooming periods, to add variety, and to supply color in the foreground. They should be planted in such a way as not to leave a noticeable vacant space in the border when through blooming. The principle motive in establishing a flower bed should be to keep it in bloom as long as possible, and annuals are a very great aid in accomplishing this end.

Perennial Delphiniums, ranging in height from low forms to tall kinds, are very useful in the flower border, because of the striking inflorescence, and the almost equally attractive foliage of many varieties. They never

seem to intrude upon other flowers. Pink Snapdragons make a splendid showing when planted in front of Delphiniums. Yellow flowers also make a good showing grouped with Delphiniums.

Snapdragons might well be called a "buffer" plant among other flowers, for, if the varieties intermediate in size are used, they seem to harmonize with most flowers, and are a material aid in extending the blooming season. They are equally pleasing when massed together, bright yellows being eliminated, or when interspersed amongst other flowers. Clarkias can be combined successfully with Snapdragons.

Single Petunias with Verbenas make a happy combination, the colors of both usually blending well, neither plant crowding out the other. Verbenas bloom a long time, make an effective ground cover, and make a colorful showing in the immediate foreground of flower borders. To prevent too straggly a growth they should not be watered too much. Asters can be planted behind Verbenas, or can be interspersed amongst late-blooming perennials with similar colors; Clarkias look well with Asters.

Some perennials because of their long blooming periods and blending qualities should be planted extensively in flower beds. Among these should be included: Pentstemon, Sweet William, Columbine, and Shasta Daisy. The Improved Scabiosa, sometimes called Mourning Bride, with finely cut foliage, and with blooms having light or deep shades of pink, red, lavender, purple, or pure white, create a delightful effect when interspersed here and there in the flower garden.

Zinnias and Salpiglossis, to my notion, are best placed in small groups by themselves, although quite effective when occasionally used as "accent" plants among other flowers. I have found it difficult to get Pot Marigolds (*Calendula officinalis*) to blend with other flowers, although especially effective, planted in front of evergreens. *Coreopsis* and *Calliopsis* should usually be planted in small groups, with some white-flowered plant inserted between them and flowers of different color. Blue Cornflowers can be planted with *Coreopsis*. French and African Marigolds because of their decided colors should be set apart from other flowers.

The above combinations of flowers are merely suggestive, for many more could be worked out, but an attempt has been made to describe groupings of flowers which meet with popular favor, and which are easy to grow.

SPRAYING FROZEN PLANTS

TOUCHING on this subject as mentioned on page 296: I am under the impression that the water must be absolutely ice cold, otherwise injury is aggravated, at least, when the subjects are exposed to the open air. On one occasion I ventured out very early and sprinkled a number of cordon and bush apples and pears that were in full bloom. The frost was so severe that I figured all the open bloom was certainly ruined but I took a chance and drew some water from the faucet. Believe me, almost as soon as the water touched the flowers the petals turned brown. When the sun got up and the frost disappeared, the trees looked as if they had been scorched by fire. I scarcely had a fruit on any of the sprinkled trees, and after that, I let the frost do its worst, preferring to remain in bed. Four A. M. on a frosty morning has no attraction for me unless necessity calls for it.—T. A. W.

Let us have faith that right makes might, and, in that faith, let us to the end dare to do our duty as we understand it. ABRAHAM LINCOLN.

What Shall We Plant for a Hedge Next Spring

FLORUM AMATOR

WHAT shall we plant for a hedge next Spring? The answer depends on whether we would like a hedge of thorny or thornless, deciduous, or evergreen shrubs or trees.

Let us assume that we should like a hedge of deciduous, thornless shrubs or trees. In these there is a choice, among those of suitable shape and size, between those notable for the beauty of their foliage especially, or for their flowers, or their fruit, or for two or all of these features combined.

If we are resting our choice upon handsome foliage chiefly, there are available several species of *Ligustrum*, privet. The best known and most widely used is *Ligustrum ovalifolium*, California privet. This shrub maintains the green color of its foliage well into the Winter and retains its foliage in a more or less green state in the latitude of New York usually until its new leaves appear early in the Spring and is therefore a semi-evergreen. Privet grows at its best in the East along the sea-coast and for about ten miles inland, from Massachusetts south. In sections where the temperature is always above zero, this privet is hardy, but in a temperature of ten degrees or more below, it is liable to be killed almost or quite down to the ground.

California privet should be set for a hedge in a single row, preferably in the Spring, about nine inches apart, and immediately after the shrubs are set, they should be cut back to within six inches of the ground. This privet should be pruned several times each season, and at each pruning cut back to within a few inches of where its newest growth started. It should not be allowed to increase in height more than six inches a year. The sides should be kept vertical as a projecting top shades the bottom of the hedge and discourages growth at the very point where density of the branches is most desirable. There is another species of privet which may be used for a hedge, namely, *Ligustrum ibota*, variety *regelianum*, which is said to be very hardy.

Passing from the half-deciduous, half-evergreen privets, used in hedges particularly for their handsome foliage, we find a long list of absolutely deciduous shrubs (that is, shrubs which drop their leaves as soon as struck by the heavy autumnal frosts) which are available for making hedges. Let us consider several of these. *Deutzia gracilis* is an excellent shrub for forming a low hedge. It bears pruning well, has a soft foliage, and in June is well covered with pretty bell-shaped white flowers. This deutzia is one of the most satisfactory of all low growing deciduous shrubs for a hedge.

Among the Spiræas, which are all deciduous, there is one variety very suitable for a low, and another for a somewhat higher hedge. The first is *Spiræa Bumalda*, variety "Anthony Waterer." In early Spring the new leaves which this shrub put forth often show to a considerable degree variegations of green, red, and yellowish white. Anthony Waterer produces continually pretty rose-colored flowers from June until October. Pruning into shape after each crop of flowers to the extent of cutting off the dry flowers and cutting back well at the time the branches which bore them, encourages rather than prevents blooming. This spiræa has also the merit of being notably free from insects. The other spiræa most suitable for a hedge is the beautiful white-flowered *Van Houttei*, which naturally grows to a height of about six feet but can be kept lower by pruning. It is a remarkably graceful shrub, and

is well covered with a wealth of pure white flowers in the Spring. When grace rather than severe regularity of form is desired in a hedge, *Spiræa Van Houttei* will certainly satisfy.

The several other species of spiræa suitable for a low hedge are, namely *Spiræa Bumalda*, the most dwarf of all, growing to a height of two feet, having pretty cut leaves, and producing rose-colored flowers through Summer and Autumn; *Spiræa callosa* growing to a height of about three feet, whose bluish green leaves are purple when young, and whose rosy flowers continue to appear almost throughout the Summer.

When a higher and stronger, but a thornless hedge is desired, we may plant out *Carpinus betulus*, European hornbeam. This tree, rather than shrub, whose oval leaves change from green to golden in the autumn and present them as well as when in their Summer color, a pleasing sight, makes an excellent hedge especially where a wind break is required and can be allowed to grow to any height for that purpose.

Fagus sylvatica, the English beech tree, and a variety of this, *purpurea*, whose leaves in Spring are a deep purple turning later to crimson, and in Autumn to a purplish green, make beautiful and strong windbreaking hedges.

Reverting to flowering shrubs which may be used for hedges, we have *Syringa vulgaris*, the common syringa, or as it is more generally called, lilac. Where a rather tall hedge is sought and regularity of outline is not regarded of so much importance as an abundance of handsome sweet-scented flowers, each May, this syringa makes a most satisfactory hedge.

There are several brier—or spine,—or thorn-bearing kinds of shrubs and trees which may be used as hedges either because their thorns restrain people or animals from passing through a hedge formed of them, or because, aside from this feature, they make by reason of their form, foliage, or flowers, an attractive hedge.

Berberis Thunbergii, Japanese barberry, a spine-bearing shrub, has many merits as a subject for a hedge. It transplants well, bears pruning sufficiently at least to keep it at the same height, is not inclined to grow tall, but has a somewhat spreading top and is therefore easily kept at a height of not more than three or four feet. Its delicate and pretty leaves in the Spring and its dropping racemes of yellow flowers are delightful to the eye. The beautiful red to which its leaves turn in the Autumn gives it a brilliant effect and the scarlet fruit with which this barberry is covered, not only throughout the Autumn and Winter, but well into the Spring, fairly dazzles the eye.

The several varieties of *Rosa rugosa* may be used in forming a hedge. The heavily furrowed leaves of this rose, which are almost evergreen, are a prominent feature and so are its spines. Its flowers, too, some white, others red, some single, others somewhat double, make a brilliant showing and the orange red hips or fruits of large size, following the flower and remaining long on the bush, prolong the bright display.

Crataegus oxyanthus, English hawthorn, is a much larger growing subject than *Berberis Thunbergii* or *Rosa rugosa*, and has strong thorns. This shrub, or tree, has pretty foliage and single, white flowers, followed by red fruits which remain on late. There is a variety of this, *C. oxyanthus flore pleno*, which bears double white flowers. *Crataegus crus-galli*, cockspur thorn, is valuable for forming a restraining hedge. This is a native crataegus, posses-

sing very long, sharp thorns, and bright red fruits. It is very showy.

Cydonia Japonica, Japanese quince, also is attractive as a Spring hedge. Its brilliant scarlet flowers appear in great profusion in very early Spring and are followed by pear-shaped yellow fruits.

Gleditsia, or *Gleditsia triacanthus*, thorny honey locust, which is armed with thorns three to four inches long, is a rapid growing tree and makes a formidable hedge. Long twisted pods follow its flowers, and though so thorny, this tree has a delicate, handsome foliage.

Maclura aurantiaca, Osage Orange, makes an impenetrable hedge when carefully set. Planted singly this grows into a medium size tree, but when used in a hedge, can be kept at the desired height. This tree is very spiny; has bright green leaves, which turn yellow in the Autumn, and bears inconspicuous greenish flowers, followed by inedible greenish yellow fruits. This has been much used as a hedge plant in the Middle West and is hardy as far north as Massachusetts.

Several species and varieties of *Thuja* make excellent evergreen hedges. *Thuja fastigiata*, or *pyramidalis*, has a compact dense habit of growth, a columnar form, and light green foliage. This is known as the pyramidal arborvitæ. *T. occidentalis*, the common American arborvitæ, has short horizontal branches, scaly, bright green leaves, with a yellowish under color; *T. occidentalis*, "Little Gem," is very dwarf, growing broader than high, and has dark leaves; while *T. occidentalis lutea*, known as George Peabody's Golden Arborvitæ, *T. occidentalis Wareana*, or *Sibirica*, has a pyramidal form, a dense and lower growth and stouter branchlets than the species itself, and glaucous green leaves. All of these arborvitæ are favorites for evergreen hedges, the choice largely depending on the desired height, the form of growth, and the color of the foliage.

Taxus baccatus repandens, English yew, will grow in almost any position and is the hardiest of all the prostrate yews. Its slender pointed leaves have an upward curve and are a lustrous green. *Taxus cuspidata*, or *capitata*, and *T. cuspidata nana* or *brevifolia* are both suitable for hedges. The species *cuspidata* keeps its fresh color all the year round, endures our severest Winters, and is an upright, fast grower. The variety, *nana*, has a rich, deep green, short foliage and a spreading growth.

Tsuga canadensis, hemlock, is a graceful, handsome evergreen. The pendulous, slender branches of the tree give to a hedge a soft effect not to be obtained through any other evergreen. It is an excellent evergreen for forming a wind break hedge.

Picea excelsa, Norway spruce, is a tree of pyramidal form attaining a height of forty to fifty feet, but is suitable for a hedge. The spruce has a handsome dark green foliage, is very hardy and makes, perhaps, the heaviest and tallest hedge of any of the evergreens.

Passing from the evergreens and conifers, we have available for a hedge two broad-leaved evergreens. The first is *Ilex crenata*, Japanese holly, which is a rapid grower; has small green, smooth oval leaves, and forms a compact, dense bush which, like boxwood, can be pruned into various shapes. The second is *Buxus sempervirens*, without argument one of the finest of all hedge shrubs and excellent for that purpose in a latitude and location where it will be neither killed by an extremely low Winter temperature or burned brown by Winter's winds or Summer's sun.

There are some factors in the problem of making a good hedge to which close attention must be given. The ground where the hedge shrubs or trees are to be planted should be dug up to the depth of two or more feet. A spread of stable manure, six to ten inches deep, should be thoroughly dug in and incorporated with the soil in the

Autumn, if the hedge is to be set in Spring, and *vice versa*. If this has not been done in advance, it is not advisable to use any stable manure just before setting the hedge shrubs for the roots to come in direct contact with, but to incorporate a moderate quantity of pure ground bone in the soil and to apply more of this on the surface after the shrubs are planted during the growing season and to rake it into the soil, or to apply sheep manure to the surface in the same way. These applications may be made several times from early Spring till mid-Autumn. After the ground is frozen a few inches deep in early Winter each year, a spread of stable fertilizer may be applied as a top dressing. This will keep the ground from alternate freezings and thawings.

Shrubs and trees of nearly the same height should be planted together in making a hedge. This is especially necessary in the case of some broad leaved evergreens such as boxwood, where to prune back severely to make the shrubs of the same height would be to cut back into the old wood and disfigure the shrub. The height to which it is desired that the hedge grow should be decided on approximately soon after the hedge is set. The hedge, however, in the case of larger shrubs and trees should not be allowed to reach its full height in one season's growth, even where that is possible, and perhaps not in several seasons. In most instances, in pruning, the new growth should be each time cut back to within a few inches of the old wood, but not to it. This method of pruning one or several times during the growing season, according as the shrub is of slow or rapid growth, keeps the hedge thick from bottom to top, and broad, and at the desired height. When once a hedge from neglect of pruning begins to grow its own way, it is brought back to the desired shape, if at all, with great difficulty.

It is almost impossible to formulate exact rules for pruning hedges but a good general rule is to have a vision of what we would like our hedge to be, and then to prune each time with care so that we may realize our vision.

RHODODENDRON MAXIMUM

THE only evergreen Rhododendron which grows in the northeastern states, with an extensive Appalachian range southward to Georgia, is one of the handsomest of the broad-leaved evergreen plants which can be grown in this climate. The flowers are pink and white or nearly white and, like those of some other late-flowering Rhododendrons, are more or less hidden by the branches of the year which usually make a considerable part of their growth before the flowers open. *R. maximum* grows well in any soil not impregnated with lime and flourishes in shade and when fully exposed to the sun, but when growing in open positions it is often seriously injured by the lacewing fly which was first brought to New England on plants of this Rhododendron collected in the south. Hybrids of *R. maximum* and *R. cataebicense* hybrids have been raised. One of the earliest and best known of these hybrids, *R. delicatissimum*, has lustrous foliage and white flowers tinged with pink which open two or three weeks before those of *R. maximum* and are not hidden by young branches. This hybrid is one of the hardiest, handsomest and most desirable of the large growing Rhododendrons which can be planted in Massachusetts.—*Arnold Arboretum Bulletin*.

Efforts to be permanently useful must be uniformly joyous, a spirit all sunshine, graceful from very gladness, beautiful because bright.—THOMAS CARLYLE.

The most manifest sign of wisdom is continued cheerfulness. MONTAIGNE.

The Beautiful Christmas Tree

BERTHA BERBERT-HAMMOND

THE idea of using an evergreen tree as the chief symbolical decoration at the Yuletide festival dates back to ancient times. The practice spread from the Teutons to other European nations, and then to America, where the custom of using a gayly spangled, gift-laden evergreen tree at the Christmas celebrations is now the general usage, there being, according to statistics of the forest service of the U. S. government nearly five million young evergreen trees marketed at Christmas time, one and a half million of these being required to supply the demand of New York State and the New England States. These figures loom up large, and read without a wider knowledge of conditions would seem to indicate a great waste of our natural resources. Probably, if closely and coldly reckoned in terms of dollars and cents, our country's wealth would be slightly increased if so many evergreens were not annually cut down, but great wealth is not the only factor to be considered in this connection. The joyful anticipation, the great pleasure, and happiness that these Christmas trees bring to rich and poor, old and young, wherever the light of Christianity has penetrated compensate mankind a hundredfold for any pecuniary loss that may be the direct result of cutting the young evergreen trees. Moreover, many of the trees used have been raised expressly for the purpose, and growing them furnishes a profitable side industry. In some of our States the trees used at Christmas would be weeded out anyway as the land needs to be cleared for improvements, so that the number of trees that have been thoughtlessly sacrificed is proportionately small.

In the cutting of trees for the Christmas trade the rules applied in forestry must be observed. Trees that are not crowded should not be taken nor should tall trees that are the result of years of growth be shamefully mutilated by cutting out the tops. Evergreen trees on watershed areas also must be protected, but if only the surplus growth of the forest is thinned out, the cutting of the trees will be an advantage and not a damage to the woodland as the following experiment will attest: A year or two ago the Government Forest Service, as a trial, thinned out the young growth on about three acres of land belonging to the Pike National Forest, Colorado, leaving about 750 selected trees (whose growth was not hindered) standing on each acre of the land. With the impediment to their progress removed these trees having freedom will add greatly to the wealth of the forest and still the young, crowded growth cut out yielded to the government the sum of three hundred dollars.

Though in the past there has been much of the prodigality characteristic of Americans, our forests still cover about 550,000,000 acres, or approximately one-quarter of the area of the United States, and now that our people have awakened to the fact that forests are a National asset, and that it is high time to practice scientific forestry methods, for the protection and perpetuation of standing timber and for the reforestation of denuded lands on the millions of acres of idle land not adapted for agriculture, but quite suitable for the growing of trees, it is reasonable to believe that having learned the lesson the people of this progressive country will be quick to take measures for the maintenance and preservation of forests for their own benefit and that of future generations. But even so, it is possible for American families to enjoy the treat of a real Christmas tree, for forestry methods that do not provide for the use of trees are a failure, because they are not practical. Realizing how much true

joy humanity receives from Christmas trees, the evergreen trees required for that purpose could be put to no better use. One may admire the sturdy oak, the spreading elm, the symmetrical sugar maple, the fragrant linden, the graceful willow, the ornamental catalpa or erect Lombardy poplar, but prompted by tender feeling and fond association the thought remains that

Sing of this or that tree,
Growing here and there;
All around the world, dear,
Every tree is fair.
North or South it may be,
Maybe East or West;
But take them all in all, dear,
The Christmas tree is best.

And though the charming old custom of having a Christmas tree is one of deep sentiment and not of prosaic economics, the idea has increased in popularity, and has broadened until at the present time, in addition to the home tree, we have the out-door community tree. For this purpose a large, well-placed, symmetrically formed, living tree is selected, and its many beautiful, spreading, evergreen branches are wired for lighting with multi-colored electric bulbs, and decorated with glittering ornaments, while once a year at least the people of the community, catching the true Christmas spirit of universal unselfishness and "good will toward men," get together and join heartily in the celebrations. As long as this country and its vast wealth exists, nothing should allow the passing of the joy-giving tree without which Christmas would lose much of its charm.

ELEAGNUS ANGUSTIFOLIUS

A TREE with silvery white foliage can sometimes be mixed with advantage with dark-leaved trees to produce contrast in the landscape, and for this purpose no tree which is hardy here at the north is so well suited as the Oleaster, as *Eleagnus angustifolius* is sometimes called. A native of southern Europe and western Asia, it is a tree sometimes thirty feet high, or a large arborescent shrub, with erect and spreading, sometimes spiny branches, and narrow lanceolate leaves up to three or four inches in length. The fragrant flowers are produced in few-flowered clusters in the axils of the young shoots and are nearly half an inch in length with a bell-shaped tube and four spreading lobes. The fruit is oval, half an inch long, yellowish and covered with silvery scales; the flesh is sweet and mealy.—*Arnold Arboretum Bulletin*.

"America is not to be made a polyglot boarding house for the money hunters of twenty different nationalities who have changed their former country for this country only as farmyard beasts change one feeding trough for another. America is a nation. No man has any right here and no man should be permitted to stay here unless he becomes an American, and nothing else."—THEODORE ROOSEVELT.

We live in deeds, not years; in thoughts, not breaths;
In feelings, not in figures on a dial.
He most lives
Who thinks most, feels the noblest, acts the best.
—FESTUS.

Early Spring Pansies

REFERENCE is made in the article on the pansies, translated from the German by F. B. M. to *Viola tricolor* which "through the course of many centuries," etc., etc. Assuredly the author was writing for the edification of the German people and maybe he meant to imply that the Fatherland was responsible for the modern pansy.

As a matter of fact, it was not until 1813 or 1814 that Lord Gambier and Thompson, his gardener, started out to improve the wild *V. tricolor* of Britain. Thompson carried on for thirty years, but it was not until 1830 that the regular blotched pansy was evolved. It was in the early 30's that the English pansy, as it was then, was introduced into France and Belgium, where the growers, heeding not the English ideal of the show types, developed what we now call fancy pansies. Probably the German fanciers did not take up the pansies until around the 50's, for the Belgian strain did not get back into England till 1858.

As to the violas, it is common news that these have held a leading position as bedders in Great Britain for the past 30 years or more; in fact, James Grieve was working with *V. lutea* and other species way back in 1860, and around that time *V. cornuta* came in for a boom, especially when the variety "Perfection" appeared in 1870 or earlier. Dr. Stuart introduced the rayless violas in the early 80's, these being from *V. cornuta* x Pansy "Blue King." Grieve did an immense amount of work with violas, all of which possessed *V. cornuta* blood.

These hybrids, of course, are larger and rounder than the *cornuta* type; in fact, they rival pansies for size and form. While some have the habit of pansies, the real bedding violas are compact, hence the name, tufted pansies. There are hundreds of varieties and the sales in England and Scotland total millions annually, all being propagated from cuttings.

Regarding the true *V. cornuta* type, "George Wernig," I think, was never anything more than old "Perfection." "Papilio" is not as good as "Lord Nelson," but all retain the smaller foliage and compact habit of the species. For compactness, however, the strain, *admirabilis*, is better, although the flower stems are shorter.

As to earliness, even a native American can smile at the thought of *V. cornuta* and its varieties being earlier than the pansy developed from *V. tricolor*, or the tropical viola. In England, it is common to find violas flowering before the Winter is over and pansies sown in late July in New Jersey will, in an open season, often be flowering before Christmas. Last year one grower lifted hundreds and sold them before Christmas, but *V. cornuta* proper certainly will not flower in anything like the same period.

Judging by the name, the so-called German *cornuta* sorts are nothing more than Winter blooming pansies offered here. These so-called Winter pansies, grown under the same conditions outdoors, will, I find, bloom a little earlier than the ordinary sorts in the Spring. I was aware they originated in Germany, although some are apt to think they originated in America, but I certainly did not know they claimed special relationship to *V. cornuta*. If they have that relationship, they are little better than mongrelized pansies and if *V. cornuta* is connected with them, it has been eclipsed by the pansy parentage, both in the way of habit and flower. None of them come anyways true to color and they vary in form. The only hint that *V. cornuta* is in them is their ability to bloom. I have a few, "Winter Sun," "March Wizard" and "Mars" (Celestial), on my rock work which have

bloomed from April till the present time. Straggly now, of course, but to compare them with the really good pansies is farcical. Under glass, they do, I believe, yield a crop in Winter, but that phase of growing pansies does not really interest me. As I am mighty particular as to the class of pansy which I grow, I certainly won't worry about the so-called Spring sorts, not while I can have real pansies and real violas.—T. A. WESTON.

SCENTED MUSK

FLORUM AMATOR appears to claim that the scentless musk is an improbability, and that what was formerly scented must of necessity be scented now. I am not familiar with any other plant formerly scented but now scentless, but I may mention that it is generally admitted that many modern roses, sweet peas and carnations are deficient in perfume compared with earlier forms. Cross breeding and striving after size and form is supposedly responsible, but with musk, no such offence has ever been committed. The perfume has simply vanished, and whether one raises seedlings or propagates by division, the results appear to be the same.—T. A. W.

THINGS AND THOUGHTS OF THE GARDEN

(Continued from page 328)

beauty in trees and shrubs in Winter, and the delicious ones which are so largely ignored at that time have many points of beauty which we would be well repaid for appreciating.

* * *

Very common expressions are heard to the effect that a heavy fall of snow "is as good as a dose of fertilizer," and the "snow is the poor man's fertilizer" when it comes in Spring. That there is some value to both snow and rain water has been proved by F. T. Shutt, chemist of the Dominion of Canada in a recent report issued. The experiments were limited to determining the amount of free ammonia, albuminoid, and nitrous and nitric nitrogen. During the year seventy-nine samples of rain and twenty-five of snow were analyzed. The total precipitation amounted to 844 mm., of which 594 mm. were rain and 250 mm. were snow (10 mm. of snow equals 1 mm. of water). The total amount of nitrogen applied by these precipitations were 7,971 kilograms per hectare (a kilogram equals 2 lb. 3 oz., and a hectare equals 11,960.33 square yards). It was found that the total amount of nitrogen supplied by rain and snow over a period of ten years averaged 7,375 kilograms per hectare annually. This goes to prove that there is some fertilizing value in rain and snow, and perhaps accounts for the fact that many skilled growers always emphasized the value of rain water for such plants as ericas, exacris and orchids as giving them just the necessary plant food desired.

Learn these two things: never be discouraged because good things get on so slowly here, and never fail daily to do that good which lies next to your hand. Do not be in a hurry, but be diligent. Enter into the sublime patience of the Lord. Be charitable in view of it. God can afford to wait; why cannot we, since we have Him to fall back upon? Let Patience have her perfect work, and bring forth her celestial fruits. Trust to God to weave your little thread into a web, though the patterns show it not yet. GEORGE MACDONALD.

Alpines Under Glass

THOUGH, in some quarters, a prejudice still exists against growing alpines in any other way than in the open air on the rock garden, there cannot be any doubt that alpine house culture for these beautiful plants is gaining fresh adherents every year. Artificial? Yes. But so is the rock garden, when compared with the free open mountain and pasture land, and a system of culture which provides such a charming effect during February, March and April as the alpine house affords does not merit much criticism. True, that everything is confined in a pot or pan and set in rows confined within four walls; but when so displayed the plants become individuals and less one of a crowd, so that their exquisite beauty and charm appeal with far greater force and are much more highly appreciated.

Though I have singled out February, March and April for special mention, do not let us overlook the fact that this is the flower time, and that by judiciously selecting the plants that are to be grown, the house may be crammed with interest, even as early as December, when, as a rule, the average garden has but little of interest to show. One is called upon to stoke no fire, so that cost is reduced to a minimum; one has no worry as to whether Jack Frost has nipped in and ruined the labor of months; while the house is left vacant just at the right time to fill up with tomatoes or Summer flowers, as the owner's fancy may dictate.

The questions arise: "What kind of house is the best for growing these miniature gems?" "What are the other necessary accessories?" and "When is the best time to start?"

The first essentials is that it should be a span roof building (preferably running north and south), not too lofty and right out in the open, so that it will not be shaded either by trees or buildings. It must be unheated. Let there be no doubt on that point: heat, even the gentlest warmth, is not only unnecessary, but positively harmful. Many and many a house that has been used as a greenhouse and that is fitted with hot water heating can be adapted by the simple expedient of not using the fire; but no heat must be used—that is final.

The sole object of an alpine house is to afford protection against rain, snow and wind, so that the longest possible period of flower perfection can be enjoyed, so that free and abundant ventilation is of the utmost importance. Too much emphasis cannot be laid upon this; a damp, clammy atmosphere being, with artificial heat, one of the two things which the plants will not tolerate. Bottom, side and top ventilators should be provided upon the most generous lines, so that night and day, unless under most exceptional circumstances, a current of air will be passing through the house, carrying away all superfluous moisture with it. The roof ventilators ought not to be quite closed at any time, those below the stage and at the side being used according to the state of the weather. A closed staging is best, consisting of a layer of slate upon which a couple of inches of coke breeze have been spread, though proper facilities must be provided for draining this or it will produce damp.

So much for the house and its fitment, but—in addition to this—provision must be made for the happiness of the plants at other seasons of the year, while they are not occupying the house. The most satisfactory, from the cultural point of view as well as saving labor, is an ash bed in the open ground where the pans can be sunk to the rim and so kept cool and moist.

This leads us, naturally, to the best period at which to make a beginning, the material to use, and general cultural management. Personally, I think there is no better period than Autumn, for so many plants can then be potted on, so many seedlings have made good progress and so many bulbs can be procured from the dealers, that one is sure of a very good display the first Spring. Apart from the consideration of bulbs and seedlings, however, there is no season, except the middle of the Summer, during which a good beginning cannot be made.

Of bulbs and tubers which can be planted during the next few weeks a special note should be made of the following: *Anemone blanda*, with its splendid starry blue flowers; *Anemone nemorosa Robinsoniana*, the finest and choicest variety of our Wood Anemone; Crocus species; Dog's Tooth Violets; *Fritillaria aurea*, and *F. citrina*, *Melagris*, *persica*, *pubida*, and *recurva*; Irises in a large range of species, such as *alata* (which flowers before Christmas) *Bakeriana*, *orchioides* and *reticulata*; and *Muscari* in both white and blue. Among the most charming plants of all are the miniature *Narcissi—cyclamineus*, *Bulbocodium*, *minimus* and *triandrus*; while, as brilliant companions, the little known but interesting dwarf Tulip species provide us with a host of pans for successional purposes. Everything in the way of dwarf bulbous rooted plants is very attractive and the flowers open in spotless purity under the glass protection.

Of other plants it would scarcely be possible to write exhaustively within the limits of an article, but Primulas and Saxifrages alone (to mention but two genera) would be sufficient to furnish a large house for many weeks with such a display of lovely blossom as few who have not experimented with indoor alpines would be disposed to credit. Just think for a moment of the various beautiful flowering "Saxies": the red "mossies," delicious alike in bud and blossom; the earliest tufted gems, such as *Burseriana gloria*; the *Megasea* section; and then the gracious encrusted forms. One can scarcely imagine a more dignified picture among all the wealth of the tropics than a fine example of *Saxifraga longifolia* in full flower. The great arching stem, rising one and one-half feet to two feet high, smothered with myriads of its white flowers, springing from a huge rosette of silvery foliage, forms a glorious picture indeed.

With Primulas, too, the story is the same, save that here is an even greater diversity of form, color and perfume. It is one of my dreams to possess a small house, filled entirely with hardy Primulas, in some future April and May that is to be and, when I do, I know that the result will prove that this is not the madness of an enthusiast, but that a real garden picture will result, a picture crowded with varying form, aglow with vivid color and crammed with interest to garden lover, flower lover and botanist alike.

But even yet we have not exhausted possibilities. There is still a mighty host of Achilleas, Adonises, Campanulas, Daphnes, Ramondias, Herberleas, Scillas, Sempervivums, Statives, Trilliums, Violas, etc., that are no less interesting or beautiful. From the end of May onwards, all the plants should be taken into the open again and plunged to the rim in the ash-bed where a couple of good waterings a week will be all the care that they need. Two of these ash-beds are better than one, although both must be in an open position and not overhung by trees. One must be in shade and another in full sun so that all classes

(Continued on page 338)

The Greenhouse, Month to Month

GEORGE F. STEWART

THIS part of the year, late December, and early January, is on the whole better for greenhouse work than that covered by last month's notes. Although, as a rule, the weather is much colder and the wind more cutting, we have clearer atmospheric conditions and by the end of the first week in January, the daylight is easily seen to be lengthening. The ancients, who used lunar time, called this period their tenth month, hence the name December. The more devout and thankful among them called this "The good and excellent month," because at this period after the long drought the "latter rains" fell, and filled the cisterns and pools and watered the dry and parched ground. In this great western country of ours, we gardeners would be very thankful for "latter rains" falling here during December, filling our evergreens with plenty of moisture before Winter sets in. I am wandering into Mr. Golding's department, so I had better get back to the greenhouse.

At this season the greenhouse looks quite gay with color. The Lorraine type of begonia is at its best; so also the tuberous rooted *Socotrana* hybrids. We have noticed that several of the varieties of these can be kept flowering over quite a long period, if kept in a cool airy atmosphere and carefully watered. The Lorraine type I have kept well through March. Mr. Peterson of Cincinnati claims begonias can be kept in bud for a long time in a light cool house, and when wanted to open their flowers if taken into a similar house a few degrees warmer, will open out beautifully, and with a much better color than around Christmas. Begonias with *Socotrana* blood in them are certainly the finest hybrid plants I have seen since 1883, and no honor too great can be bestowed on such men as Lemoine and Heal for their pioneer efforts among the two distinct types of begonias referred to.

While we are speaking of valuable plants introduced for greenhouse purposes, *Asparagus Sprengeri* deserves, to be also placed in the front rank, both for cutting and as a pot plant. I remember some years ago talking with a one time gardener, he was then in the greenhouse business and also interested in quite a large nursery, who told me that while traveling in Italy, he saw the first of *A. Sprengeri* that came to Europe. It was in full fruit when he saw it, and could have been purchased for quite a small sum of money. If I remember rightly he could have secured the plant for twenty-five dollars. I asked him why he did not buy it. "I never thought it would take the market the way it has done," he said. As you may guess, he was Scotch, and you know, we are blamed for being cautious on the wrong side.

Sow fresh seeds of *A. Sprengeri* now; keep them well soaked with water until they germinate, and keep them in the warmest corner of the tropical house. Cover the receptacle they are sown in with a pane of glass until the first shoot appears, and then allow them to dry out considerably before watering again. Fresh seeds will germinate quite freely, but old seed will straggle along for two years, not coming even at all. A good plant grown in a basket in the full sunshine will give a private place all the seeds it requires, and besides, it is a plant of beauty grown in this manner. Small plants in six-inch pans are very effective for edging a group of plants, and are not as stiff looking as any of the *Nephrolepis* varieties of ferns

we often see used for that purpose. A good strong rich loam is all they need to grow in.

Any of the begonia leaf cuttings is better if potted in a suitable size of pot, when they throw up a shoot from the base of the leaf. Equal parts of flaky leaves (preferably beech or oak) and good fibrous loam with charcoal broken quite small we have found makes a good first potting. Personally I don't like sand in a potting compost for begonias, although others use it and grow fine plants. Any sand I have ever used in begonia growing has had a tendency to develop rust-like spots on the leaves.

Cyclamen seeds sown in August should now be ready for small pots. To good fibre of loam chopped small, and half decayed leaves that will break small when rubbed between the hands, add a little sand, and charcoal in a convenient size for small pots, also about a fourth of a spent mushroom bed. Place them close to the glass when potted and water carefully until they get established. Shade them for a few days until they stiffen up, that is, if the weather is bright.

This is a good time to root carnation cuttings. Several years ago we experimented with carnation cuttings taken from various parts of the plant. We found the following season that those taken well up the flower stem, even though they were rather short when taken off, produced during the whole season, and did not come in crops at intervals. These tests were made in an old-fashioned greenhouse which carnation enthusiasts of today would class as unfit to grow good plants in. I would not blame them very much, as it is uphill work to grow good plants of any kind in an old-fashioned greenhouse, especially in a poor location.

Roses may be also rooted now as well as any time. I believe better roses, and freer flowering, can be produced from flower stems of a medium thickness than by blind wood. The only drawback is the loss of the flowers. The same may be said of budding or grafting. Many plants can be improved, in fact, I am safe to say, all, by careful selection of the wood for propagation. The study of *Life*, whether animal or plant, the wisest of men are very much in the dark about. Let us pass around whatever we know or discover about plant life or growth. Life here is short. Eternity, do we grasp its meaning? After all, what have we, but what we have received?

Those who want to grow a few large chrysanthemum pot plants, put in cuttings in late December or early January. If rooted and shifted along as soon as the roots break through the soil, in the first potting and all later necessary shifts, very large plants in twelve-inch pots may be had in one season. In years gone by, we have had under our care plants with over one thousand flowers, from a cutting rooted about January first.

I wonder why one seldom sees a *Lapageria* now? In these days when there is so much floral decoration done on festive occasions, there is no plant that I know of whose sprays are more effective for mantle decorations. They are not at all hard to grow. A shaded cool house, or corridor, with a suitable bench, say fifteen inches deep and well drained; a compost, composed of *Osmunda* fern root, and fibre loam in equal parts, sand and charcoal to keep it sweet and porous; a liberal amount of moisture at the roots, and frequent light sprayings overhead; a temper-

ature never over forty-five degrees Fahr. in Winter, and one has ideal conditions for growing Lapagerias. After they are well established a top dressing of fresh compost as advised above once a year, together with liberal waterings with cow manure water, when in active growth, will keep Lapagerias, that are planted out, in good condition for years.

Years ago, I remember seeing a fine specimen grown in a tub with about three hundred open flowers on it. It was grown by a stonecutter, in a small sash house attached to his dwelling. No fire heat was used in Winter. A few mats over the glass on frosty nights was all that was required for protection, but that was in Scotland.

Put in some cuttings of *Pteroma elegans*. If well pinched, they will make fine Summer and Fall flowering plants.

Our tub of *Eucharis Amazonica* is just throwing up its flowering stems. We just gave it a month's drying off, and shall water it well and give it plenty of plant food for the next three months and then repeat the drying off process. By this mode of treatment we have sometimes had three crops of flowers in a year.

Plumbago rosea is another plant that flowers around this season. At sixty degrees they can be had in flower for Christmas, and can be had for later use by holding them in a temperature ten degrees lower.

Keep Poinsettias at sixty degrees when opening their bracts.

Dipladenias should be resting, by keeping them quite dry at the roots, until the end of January, forty-five to fifty degrees is warm enough to winter these plants in. They start much stronger when the weak wood is trimmed off about the middle of January, if not kept over that temperature all Winter.

This is a good time to make up some hanging baskets for verandas or other suitable locations. Ivy leaved geraniums are first class for this purpose. They can be had in several colors. Trailing Queen fuchsias are also very effective. We root a number of small plants and arrange about a dozen round the rim of the basket. We tie a few up to a stake in the centre of the basket in the form of a pyramid, or train them round the hangers. We keep them pinched and tied until about eight weeks before they are wanted to flower, and then let everything come.

Keep the gardenia house at a temperature never lower than sixty degrees at night at this season five degrees higher will give you more flowers, that is, if one has healthy plants. Syringe very little at this time of the year, as bud dropping will be sure to annoy you, if the plants are left long with wet foliage. Keep them clean by careful fumigating with hydrocyanic gas. Keep the floors well damped until one o'clock in the afternoon, which, with careful watering, will give plenty of moisture until the sun is stronger. There is time yet to make another sowing of all the garden annuals that are usually forced, and there are many others that have as yet been very little tried out for forcing purposes in this country. Many will not grow well outdoors here in Summer, yet in a cool greenhouse, with our bright clear sunny days they force well and are fine for early Spring decorative work, where large quantities of flowers are required.

Calanthe veitchii and the earlier flowering varieties will be in flower. If arranged among foliage plants in the various shades of green, they are among the finest of flowering plants we have around Christmas. The variety *Sanhurstiana* is a gem and should be included in every collection of these orchids.

Lalia anceps also flowers around this season. The general complaint is that this orchid does not keep well as a cut flower, but there will be little trouble on this score, if

one scrapes the outer bark off the flower stems about seven inches up from the end of the stem, and also splits the same with a sharp knife several inches in length. After this operation place them in warm water for several hours. *Lalia autumnalis* has just finished flowering with us, and flowering at this season, it is very useful. These two orchids we find like plenty of light Summer and Winter, fifty degrees night temperature is high enough, but we find they open their flowers better a few degrees higher. The cross-bred orchids flower at all seasons and now fill in gaps in the flowering season that old-time orchid growers had to do by manipulation of shade and temperature. A good rule is to pot all orchids, that is, if they need it, just as soon as they show the slightest tendency to root action. We do not like to disturb any of them, unless the compost is spent, or the growths run over the rim of the receptacle. We find they like oak leaves in the compost, if cut up and used soon after they fall off the trees. There is also a close growing yellowish looking fibre which we find growing at the roots of the huckleberry around here, where oak is the principal tree in the woods, and they like it better than *Osmunda* fibre. One-third of good fresh live sphagnum should also be in the compost, and, of course, plenty of broken charcoal. The possibilities of sugar in the water, as a stimulant is very little known, but remember how it is found oozing out of the foliage of a vigorous growth of some of them. It makes one wonder and think a little along that line. We observed it first about fifteen years ago, but have never had the chance to experiment, as we would like. In our climate never keep evergreen orchids too dry, as our bright strong sunshine causes quick evaporation of the sap.

It is now time to start early fruit houses. Clean and top dress the borders of the early grape house. The easiest and best flavored grape to force early is undoubtedly Black Hamburg, which sets freely, and breaks even. Start the temperature around forty-six degrees and raise it gradually to sixty or sixty-five nights, after the border has been fed a little with the standard grape foods and watered. About every ten days raise the night temperature five degrees with a day rise of about ten degrees, but do not get ugly with your assistant, if once in a while it runs a degree or two high; no harm will be done, except to your peace of mind and health. Syringe several times a day at the start. Do not tie them up to the trellis until they break equal all over the vine. There is no danger of breaking the buds, if you keep calm, and are not in too much of a hurry.

Peaches and nectarines should be started in a similar manner, only keep the temperatures about five degrees lower and do not feed any until the fruit is set. This is better to be done artificially if no bees are around. Avoid draughts in any of the fruit houses.

Strawberries may also be forced now, and all pot fruits such as apples and pears. Strawberries do well in a carnation house temperature and apples, pears, etc., similar to peaches, but being in pots they require more feeding.

If you have plenty of room, and ample assistance, keep up a succession of all forcing vegetables. Sow every two weeks. Get a good book on forcing fruits and vegetables, as in these notes we cannot go into details, as much as we would like to. There is a good one written by Wm. Turner for this climate.

The only rational liberty is that which is born of subjection, reared in the fear of God, and the love of man, and made courageous in the defense of a trust and the prosecution of duty.—SIMMS.

Work for the Month in the Garden

SAMUEL GOLDING

DURING this season, the main work in the garden is to see to it that the more tender subjects are provided with adequate protection. Many of the most attractive and decorative subjects we have, suffer somewhat in popularity because their hardiness is open to question. The position and locality, of course, plays an important part in their successful culture. Some may be condemned solely because they may have been planted in an unsuitable position.

Regarding the varied subjects, some care should be exercised in providing suitable protection and to avoid as far as possible, using unsightly material. Spruce branches are well adapted and make excellent screens, and when they are available, are more picturesque, than corn stalks. Excellent though they are for wind breaks, they should be used in the less conspicuous places of the garden. Up to the time of writing (first week in December) we have been favored with exceptionally fine and open weather, which has delayed the final application of the protecting material. It is, however, practical to have everything in readiness, as these pleasant conditions may change with great rapidity.

It has been previously referred to in these columns that rough litter, leaves, pine branches, or other material through which the air can penetrate, is the best to use, especially so for the class of plants whose foliage persists above the ground during the Winter, such as Sweet Williams, Shasta daisies, Oriental poppies, Artemisia, etc. Experience necessarily teaches the amount of covering the various plants need. It is oftentimes more dangerous to give too much than when done in a sparing manner, especially so in the case of some herbaceous plants. Where too heavy material is used, if we get a mild spell during the early days of March, the plants may start into growth, and the young shoots will probably be injured when the covering is removed.

When there is an abundant snowfall, which stays throughout the Winter, it provides a blanket which cannot be surpassed, and plants winter so much better than when we experience a succession of frosts and thaws.

The rose bushes should by now have the soil pulled up around the base; allow the ground to be well frozen up before giving the final covering. If this is done before leaves are put on, the ground will remain hard throughout the Winter, and make a less pleasant abiding place for mice which are somewhat partial to the rose bed.

Conifers and shrubs which may be injured by weights of snow, should be well staked and tied to prevent harm. They should be well shaken after snowstorms to remove the weight.

The fine weather experienced during this Fall has been most favorable, enabling one to push on with outside work, and where advantage has been taken to dig and trench, or do necessary alterations, he will be well ahead when the Spring rush is here, in fact, the advantage gained is more lasting as more time can generally be devoted to doing it well, at this season.

The mild spell has also prolonged the supply of vegetables; the Brussels sprouts, Scotch kale, and spinach have been able to continue their growth. It has also been fine weather for stocks in frames. As soon as the weather becomes too severe pull up the Brussels sprouts; pile them

together in some place, easy of access, and cover them with leaves or straw. Give the spinach a good mulch of salt hay. See that enough chicory, rhubarb, horse radish, parsnips, salsify, is lifted to ensure a supply throughout the Winter. Go through the stocks of potatoes, roots, and fruit at intervals to remove the diseased specimens. Keep the onions cool and give them abundance of air without allowing them to become frozen, otherwise they commence to make growth and their keeping qualities are impaired.

Remove decayed foliage from plants wintering in frames, admit air on every favorable day. Water them carefully; they may be kept on the dry side at this stage. Have a supply of fermenting material banked up around the frames during severe weather. Keep a sharp lookout for mice in frames where pansies and like stock is wintering. These rodents do much damage in a short time; some poisoned bait placed around is often an effective precaution. Keep up the successions of forcing vegetables where the facilities permit; renew mushroom beds as the old ones cease to be profitable.

Push on with pruning and thinning in the orchard when conditions permit. See to it that newly planted stock is securely stacked and tied to prevent it from being blown about during heavy gales. Give them a good mulch of rough litter or manure. Apply the first Winter spray, also spray shrubs that are infested with scale. Lilacs are very subject to these pests. During the Winter months ample opportunity is afforded to secure a stock of necessary tools, stakes, flats, etc., that will be needed in the early Spring. Anything that can be done now along these lines will be a real time-saver when many other important details are pressing.

December is generally alluded to as the gloomy month, but where a garden has been planned and planted with an eye to Winter effects, this garden is never devoid of interest. A tree when covered with snow or ice glistening in the sunshine is a thing of great beauty, which soon passes away, but a judicious planting of varied shades of evergreen, berried plants, deciduous shrubs of colored twig, bark, and stem, all combine to make the garden a joy from January to December.

ALPINES UNDER GLASS

(Continued from page 335)

of plants can be suitably accommodated, Primulas, Cyclamens, Trilliums, etc., going into the shaded bed; sun-lovers such as the Saxifrages, Sempervivums, Irises, etc., enjoying the one in fullest sunshine.

The alpine house certainly provides us with one of the cheapest, most interesting Spring features in the garden and one can but hope to see an even larger extension of such a beautiful feature in the near future.—*The Garden (British)*.

There are two freedoms—the false, where a man is free to do what he likes; the true, where a man is free to do what he ought.—CHARLES KINGSLEY.

The constant duty of every man to his fellow is to ascertain his own powers and special gifts, and to strengthen them for the help of others.—JOHN RUSKIN.

THE PERFECT ROSE.

While very few will be found to disagree with the dictum that in the rose we have developed a wonderfully perfect variety of flowers, there remains the extraordinary fact that among the hundreds of varieties in cultivation we have achieved a standard of perfection only in a curiously small number.

It is possible to say that under critical judgment no rose at all answers the tests which would be applied to a standard of "100 per cent. perfection" if such a standard were devised by rose-growers and rose-showers. Let us consider for a moment what such a standard would be, and what requirements the perfect rose must display: The double roses would undoubtedly take first rank; undeniably beautiful though other types are, the true rose of culture is a "double"; and a double of that degree which is full-petaled. But petals are not all: There must be form. Here again there is a catholicity of taste to be catered for; the exhibition-type of fullness which is a whorl of regularly-disposed petals round a high-pointed centre is loveliness indeed, but this type has not the total claim on "form" in roses.

Color brings us to a divergence of opinion again, for one may condone form-faults and petal-shortages to include in a select list those roses whose color may bring a strong appeal to the judge's table. Who would withstand the appeal of a real deep red rose as compared to a pink, for instance?

Habits of growth then require to be considered—and once more many prime favorites will be ruled out because they are not easily accommodated: The bush-type of Hybrid Teas will win in this selection, as a class; but the gorgeous flowers of many grand roses of this free-growing class must fall away because we desire rose-bushes of compact shape and habits. And lastly, we must consider constitution; and constitution is a test that so many, many more of our rose-queen aspirants will succumb to. There must be vigor, and there must be a definite tendency to withstand diseases and pests. What grand roses are lost to us, because however great their inaugural triumphs they have "failed to grow."

So much for "the perfect rose." Shall we find it among the reds, the whites, the yellows, the pinks, or those roses which almost defy a color-description, the Pernetianas.

We come next to a class, the Decorative Roses. In the garden-roses, which is another name for what are described as "decoratives" in Europe, we have a little confusion here, for in this country we can get exhibition results "in the open," which is beyond the expectation of the Northern rosarians whose garden-flowering roses are not expected to bear blooms for the exhibition-box.

In our sunny land both will grow equally well in the open, therefore we may be excused if we find that S. A. rose-gardeners make revel with the decorative class, which has only the one fault (to the pure exhibition-rose seeker) of "fewer and looser petals." Now for garden-purposes these are no faults at all, and our rose-growing in this country is enriched by a class that is well suited to our climate and when taken as a whole, is profusely floriferous.

The semi-singles and the singles are roses which to many tastes have an irresistible appeal. Even the ultra-exhibitionist bows his head before the solid intense dull red of the incomparable Red Letter Day—a semi-single which in the half-opened stage is a wonder of coloration. And in singles, consider the color of that Irish prince of roses, Irish Elegance: it is simply marvelous, and in its strongly developed color contrasts per petal defies the competition of the double roses, on a color basis.

Ever new roses! Each year we await the awards of the great shows to see what new beauty the wizards of the rose nurseries have produced for us.

How are they produced? By very precise handling indeed: By cross-fertilizing proven colors or forms from which acceptable hybrids are anticipated. Hand-fertilizing, protection from any further crossing except the one designed; then the resultant seed-pod, the planting, and finally a flower at last; after all this trouble surely a gold medal rose! By no means! From hundreds of seedlings perhaps one or two worth carrying on with—and their potentialities hardly visible, probably quite invisible to the uninitiated eye. From the whole lot of seedlings in flower a mere dozen put back to carry on with, and hundreds for the fire. And of the selected ones perhaps not one worth "growing on," but a few maybe which display qualities that the rose-breeder recognizes as worth keeping to try and perpetuate into more promising crosses. From such a "potential" are the wonderful roses that come from Pernet Ducher's said to materialize—the "unnamed

seedling" is the parent of Madame Herriot and all her tribe.—*South African Gardening and Country Life*.

CLIMBERS FOR GREENHOUSE WALL

Given a suitable selection of plants, the wall of a greenhouse may be made as interesting as any part of the structure. To succeed with wall plants in a greenhouse by far the better plan, as with climbers of all kinds, is to plant them out. In preparing a border thorough drainage is necessary. In the case of walls that receive a good amount of light and sunshine, there are many different plants available for covering them; but, where heavily shaded and perhaps damp, the choice is very limited. In any selection of plants suitable for greenhouse walls the Heliotrope must have a place, as it will flower profusely nearly throughout the year, and a specimen of it in full bloom is very beautiful, and also extremely useful for cutting. The South African Leadwort (*Plumbago capensis*), with its clusters of porcelain-blue flowers, is also another continuous bloomer very valuable for such a purpose, while we have also seen some of the Abutilons in good condition trained to a wall. The pure white "Boule de Neige" is one of the oldest and best, while others well adapted for this treatment are *A. striatum*, yellow veined with crimson, and "Golden Fleece," deep gold. Pelargoniums, both of the Zonal and Ivy-leaved sections, will flower well, and we once saw a wall completely covered with them alone. It was in a sunny spot, and the quantity of flowers produced there was enormous, the Ivy-leaved varieties in particular producing a truss of blossom from nearly every joint. *Chianthus puniceus*, with its peculiar lobster-clawlike blossoms, is a very ornamental wall plant if the foliage can be kept clear of red spider, which is not always the case; still, a good deal can be done towards keeping it down by a liberal use of the syringe.

The various forms of *Habrothamnus* may all be employed as wall plants, but they are better adapted for pillars than for back walls. Many climbing plants, the Lapagerias, for instance, will do well in such a position, but in a general way they are hardly seen at their best so treated. Camellias are perhaps the finest of all permanent wall shrubs for the greenhouse. They also possess the merit of being almost hardy, so that a low temperature in the Winter has far less effect on them than on many greenhouse plants. The glossy foliage, too, can, with the syringe, be kept bright and clean at all seasons. The sweet-scented *Daphne indica* will succeed under much the same conditions as the Camellias, but it is rarely seen grown in this way.

In the case of a damp wall or one that is too heavily shaded for the above-mentioned plants to thrive, the better plan is to clothe it with either the small creeping *Ficus repens* or its still smaller form *minima*, both of which will grow freely in such a spot, be it stove or greenhouse. But little preparation for planting them is needed, and if the wall is fairly moist sufficient roots will be produced from various parts of the stems to support the plants. *Gardening Illustrated*.

Tall Bearded Iris, by Walter Stager. Published by the author; for sale by Madison Cooper, Calcium, N. Y.

In view of the present great and rapidly increasing popularity of the Iris a new and authoritative work on the subject is bound to meet with ready acceptance, particularly because the excellent little book of Dyke's is not only out of date but even out of print, while the sumptuous *The Genus Iris*, in addition to its lack in matters of practice, is to most persons inaccessible on account of its price. But now the lovers of "The Flower of Song," "The Poor Man's Orchid," and "The Orchid of the North," have available, at low price, thanks to the devotion of the author, a treatment from the hand of an American, thoroughly satisfactory in point of appreciation, of matters historical and literary, and of management of this plant, which, though usually most tractable, sometimes almost baffles the most proficient gardener.

The book is a revision and enlargement of a monograph of similar title distributed gratis several years ago by the author, who, after finding for many years relief from the strain of professional duties, like Joseph Jacobs among his narcissi and tulips and W. Wilks among his poppies, has become like them an authority of the first rank in his secondary field. This new edition displays, among other admirable qualities, a careful judicial temperament fostered by legal studies and practices carried well beyond the ripe old age of above four score.—F. B. M.

National Association of Gardeners

Secretary's Office: 286 Fifth Avenue, New York

The aims of the association are, to elevate the profession of gardening by endeavoring to improve conditions within it.

To cement a closer bondship among all engaged in, and interested in, gardening—to create a greater confidence between employer and employee.

The association is professional in character. It must in no wise be associated with unionism.

President—Robert Cameron, Ipswich, Mass.

Vice-President—John Barnet, Sewickley, Pa.

Secretary—M. C. Ebel, 286 Fifth Ave., New York.

Treasurer—Montague Free, Brooklyn, N. Y.

TRUSTEES (For 1922)—William H. Waite, Arthur Smith, D. L. Mackintosh, New Jersey; W. N. Craig, Massachusetts; H. E. Downer, New York.

DIRECTORS (To serve until 1923)—Alexander Michie, Long Island; George F. Stewart, Massachusetts; Theodore Wirth, Minnesota; George W. Hess, District of Columbia; Daniel J. Coughlin, New York; John Barnet, Pennsylvania; Montague Free, New York. (To serve until 1924)—William Gray, Rhode Island; William Hertrick, California; George H. Pring, Missouri; Thos. Hatton, Connecticut; Robert Weeks, Ohio; W. H. Griffiths, Michigan; Thos. W. Head, New Jersey. (To serve until 1925)—George Wilson, Illinois; James Stuart, New York; William Kleinheinz, Pennsylvania; John F. Huss, Connecticut; Edwin Jenkins, Massachusetts; Carl N. Fohn, Colorado; Joseph Tansey, New York.

SUSTAINING MEMBERS

New York—Mrs. J. J. Albright, George F. Baker, Edwin S. Bayer, Henri Bendel, Albert Clayburgh, W. R. Coe, Mrs. F. A. Constable, Paul D. Cravath, Mrs. W. Moore. *Virginia*—Miss Grace E. Arents. *W. Virginia*—Mrs. Arthur Lee. *Georgia*—E. H. Inman. *S. Carolina*—Robert S. Melbane.

LOCAL BRANCHES

Newport, R. I.: Andrew L. Dorward, chairman; Frederic Carter, secretary.

St. Louis, Mo.: George H. Pring, chairman; Hugo M. Schaff, secretary.

Nassau County, L. I.: John T. Everett, Glen Cove, chairman; John McCulloch, Oyster Bay, L. I., secretary.

Boston, Mass.: Robert Cameron, chairman; W. N. Craig, secretary, Brookline.

Western Pennsylvania: Manus Curran, chairman, Sewickley; Henry Goodband, secretary, Sewickley.

WESTERN PENNSYLVANIA BRANCH

The interesting report of the meeting of the Boston branch of the National Association of Gardeners, which appeared in the October CHRONICLE, showed of what benefit the branches can be to the members of their communities. We should have more of these branches, as they offer opportunities to members who cannot attend the annual convention, to make suggestions which can be brought before the annual meetings. It is not necessary to decide

that meetings be held at regular intervals. Just bring the local members together and select a chairman and secretary. Your chairman can then call a meeting whenever any subjects of interest to the members arise, that can be discussed with profit to the association and the profession it represents. Notify the national secretary, Mr. Ebel, that you have organized a branch and send him the names of your chairman and secretary. He will then advise your secretary whenever anything comes to the national office which should be submitted to the local branches for consideration and action.

JOHN BARNET, Vice-president.

A PLEA FOR MORE BRANCHES

A meeting of the members of the Western Pennsylvania Branch of the National Association of Gardeners was held at Ridgeview Farm, Sewickley Heights, Pa., on November 15.

Mr. Manus Curran was unanimously elected chairman and Henry Goodband, secretary, for the ensuing year. A motion was carried that each member be assessed fifty cents a year for dues to defray current expenses and that the secretary be empowered to purchase the necessary stationery, etc. It was moved and carried that a meeting shall be called at least one month previous to the annual convention, and the rest of the meetings shall be called at the discretion of the chairman.

John Barnet, president-elect of the National Association of Gardeners, and Wm. Thompson, Jr., gave a brief account of the Boston convention held on September 12-15, which proved quite interesting.

The secretary was instructed to acknowledge with thanks Mr. August Frishkone's offer of the use of his store for any of our meetings. Mr. Barnet was appointed to see Mr. Moore, of West Park, about a meeting place.

It was moved and carried that the rules and regulations of local branches as approved by the Newport, Boston and St. Louis Branches be approved by this branch.

HENRY GOODBAND, Secretary.

NEW MEMBERS

The following new members have recently been added to the association: James Guilfoyle, Southampton, L. I.; Henry Banak, New York, N. Y.; Thomas Roland, Nahant, Mass.; Martin Kuiper, Oyster Bay, L. I.; Michael Latham, Port Chester, N. Y.; H. D. Ayling, Cedarhurst, L. I.; Robert Broadbridge, Monmouth Beach, N. J.; Otto Peulecke, Ridgefield, Conn.; Salvatore Cairo, Port Chester, N. Y.; Harold Graham, Newton, Mass.; John A. Lynn, Glenview, Ill.; James Barnet, Atlanta, Ga.; Charles Stude, Somerville, N. J.

IS GARDENING A PROFESSION?

When the question arises, Is gardening a profession? I answer, Yes! Although whenever it is discussed as such there is nearly always to be found a diversity of opinion on its being so classified rather than as a trade.

That the man who merely possesses sufficient knowledge to mow the lawn, tend to the vegetable patch, and grow a few varieties of flowers, is rated as a gardener instead of a garden laborer, is no fault of the profession unless it may be charged with having been lax in making it more generally known what the qualifications of a gardener really are.

Neither has the profession any power to prohibit milady from deriving pleasure out of referring to "my garden," whose chief duties are to run a Ford, tend the furnace, do the cook's chores, and, when the nurse absents herself, look after the children in addition to his gardening. His proper title is that of handy man.

Of course, if the standard of the gardener is to be judged by all who are classed as gardeners, one might even be justified in assuming that the gardener comes within the ranks of labor.

When, however, we consider the gardener who possesses the talent and the ability to produce all that is æsthetic in the garden, he surely cultivates a fine art, which is in every respect entitled to recognition as the work of a professional. But his knowledge is not alone limited to the garden, for as the superintendent of an extensive country estate, he must have a working knowledge of agriculture, husbandry, dairying, building, road construction, power

plants, etc., in order to prove himself an efficient supervisor of the work that comes under his management.

Those who have had experience with gardeners know that the type at times portrayed by the humorist does not represent the gardener who depends on his intelligence for success. The increasing tendency to turn to the colleges to acquire a theoretical knowledge as well as the practical experience which comes to one through working in a garden, will bring recognition to the profession as being a worth-while one, one that creates inspiration, and not discontent among mankind.—M. C. E.

LOCAL SOCIETIES

THE CLEVELAND HORT. SOCIETY

At the Chrysanthemum and Vegetable Show of the Cleveland Hort. Society, Nov. 9 and 10, the quality of the exhibits was exceptionally fine, the big 'mums being of the very best. The specimen pot plants were all well grown, especially a single "Cinderella" exhibited by George Jacques. The Winter flowering begonias were also well grown plants, as were the Lorraine type. R. P. Brydon received a Certificate of Merit on the former, and a Cultural Certificate on the latter. The vegetable classes were well filled and of excellent quality. A collection of berry bearing branches taken from trees and shrubs on the estates of J. L. Severance and Mrs. F. F. Prentiss was most interesting, being one of the exhibits to cause the greatest interest in the show.

The awards for cut blooms, chrysanthemums, were as follows: 24, Mrs. F. F. Prentiss 1st, silver cup (R. P. Brydon, Supt.); 24, Mrs. W. T. White 2nd, silver medal (R. Broadfield, Supt.); 6 white, W. D. B. Alexander 1st (F. Eckhard, gard.); 6 yellow, W. G. Mather 1st (George Jacques, Supt.); 3 white and 3 pink, J. L. Severance 1st (A. Brown, Supt.); 3 yellow, E. S. Burke 1st (W. E. Fisher, Supt.); 3 bronze, J. L. Severance 1st; 9 Japanese large flowering anemone, Mrs. F. F. Prentiss 1st; 6 sprays single white, Mrs. J. D. Lyons, Sewickley, Pa., 1st (John Barnett, Supt.); 6 sprays single pink, J. L. Severance 1st; 6 sprays single yellow, J. L. Severance 1st; 6 sprays single bronze, Mrs. J. D. Lyons, 1st.

In pot plant chrysanthemums: 7" and over singles, W. G. Mather 1st; 6" singles, Miss Sherwin 1st (L. B. G. Webb, gard.); 7" and over pompons, Mrs. Knapp 1st (W. Peschke, gard.); 6" pompons, Miss Sherwin 1st; 7" and over decoratives, Mrs. F. F. Prentiss 1st; 6" decoratives, Miss Sherwin 1st; 6" anemones, Mrs. Knapp 1st.

Collection of foliage and flowering plants, W. G. Mather 1st. Collection of vegetables, E. S. Burke 1st. Six varieties of vegetables, George Hancox, 1st.

In pompon and decorative classes the awards were as follows: Six sprays pompons, white, Mrs. W. T. White 1st; 6 pink and 6 yellow, J. L. Severance 1st; 6 red, E. S. Burke 1st; 6 bronze, Mrs. Knapp 1st. Three of any color, Mr. Baker (George Williams, gard.) 1st, silver medal. Six sprays decoratives, white, Mrs. F. F. Prentiss 1st; 6 pink, J. L. Severance 1st; 6 yellow, E. S. Burke 1st; 6 bronze, Mrs. W. T. White first.

In the table decorations for ladies, Mrs. Laine won first and Miss L. Jacques second. All the carnation classes were carried by W. G. Mather.

A Certificate of Merit was awarded Hermann Rapp, Sewickley, Pa., for seedling anemone, white, "Mrs. Edna Thompson."

The judges were: J. Carman, Sewickley,

Therefore It Hath Its Charm

Isn't it hard to quite understand how some people spend unstintedly for buildings and the "doing over" of their grounds, only to secure a regrettable effect of man-madness?

Everything has the look of having been just placed there. All nature's naturalness has been ruthlessly ironed out. In contrast, you at rare intervals run across a layout that is a delight in its utter frankness, its skilled adaptation to nature's own setting.

How it prompts a long breath and a sigh of contentment.

Therefore, this greenhouse has its charm.

It just fits in the picture, as it were.

You can well imagine the satisfaction it was to do our bit in securing this result for Dr. J. H. Lancashire on his Massachusetts woodland-crested estate, at Manchester-by-the-Sea.

Why can't we do as much for you? Would you like our booklet called "Owning Your Own Greenhouse"?

WESTCHESTER AND FAIRFIELD HORT. SOCIETY

A meeting was held in Greenwich, Conn., November 14. There was a large gathering of members, and nominations of officers for 1923 were received.

One new member was elected and a fine exhibition of chrysanthemums were staged.

Prize winners in the chrysanthemum competition were as follows: Class 1—Six blooms, one or more varieties: 1st, James Stuart; 2nd, J. McCarroll. Class 2—Three blooms, one or more varieties: 1st, W. D. Robertson; 2nd, Alexander Smith. Class 3—Twelve anemones, one or more varieties: 1st, W. Sealey; 2nd, G. Hewitt. Class 4—

Six vases of pompons, six varieties: 1st, G. Hewitt; 2nd, W. Sealey. Class 5—Six vases of singles, six varieties: 1st, James Stuart; 2nd, W. D. Robertson. Class 6—Vase of pompons for effect, any foliage allowed: 1st, W. Sealey. Class 7—Vase of singles for effect, any foliage allowed: 1st, H. F. Bulpitt. Class 8—Centerpiece of chrysanthemums, any foliage allowed: 1st, W. Sealey. Class 9—Vegetables; six varieties, arranged for effect: 1st, James Linane.

The members of the society met in Greenwich on Sunday, November 26, and went in a body to the cemetery to place flowers on the graves of deceased members.

T. J. BULPITT, Cor. Sec.

NASSAU CO. (N. Y.) HORT. SOC.

The regular meeting of the above society was held at Glen Cove, L. I., on November

8. Two applications for active membership were received. President Milstead appointed S. Trepass, J. Nash and J. Mitchie to judge exhibits, and their awards were as follows: Three pink, 3 yellow, 3 white 'mums, 1st, Joe Merchler. Table decorations for assistant gardeners were keenly contested and some fine tables were put up. A table of roses of much merit, arranged by Ernest Redill, received the society's special prize. The chrysanthemum tables were also very good—1st, James Young; 2nd, Herbert Adams; 3rd, Theodore Phillips. Trubie Davison was elected to honorary membership. The report from the 'mum show was adopted, and the manager and judges were given a hearty vote of thanks.

Two hundred and seventy-three exhibits were staged at the most successful Chrysanthemum Show in the history of the society, held November 22-23. Mrs. Percy Chubb's (Peter Smith, Supt.) group of chrysanthemums was awarded first premium. Mrs. John T. Pratt (Jack Everett, Supt.) was awarded first premium for a very artistically arranged group of foliage and flowering plants and a Cultural Certificate for six fine plants of geranium grown in the old English style. For twelve chrysanthemums, four varieties, three of each, first, Mrs. E. F. Luckenbacher (Thomas Twigg, Supt.). For the best twelve varieties, short stems, first, Mrs. Percy Chubb. For the best eight chrysanthemums, one variety, first, Mrs. H. L. Pratt (James McCarthy, Supt.). For the best six yellow chrysanthemums, first, Mrs. C. A. Coffin (Joe Boehler, Supt.). Miss Alice DeLamar (James C. McMannin, gardener) had the largest bloom in the show, "William Turner," twenty-eight inches in circumference. Twenty-five varieties of chrysanthemums grown and flowered outdoors: First, Mrs. George F. Baker (James McDonald, Supt.). Best twelve varieties grown and flowered outdoors: First, Mrs. M. Daball (August Stanga, gardener). Best nine varieties of single chrysanthemums: First, Mrs. Payne Whitney (George Ferguson, gardener). Best Twelve sprays, single chrysanthemums, one variety: First, Mrs. Harold I. Pratt (F. O. Johnson, Supt.). Honors in the rose class went to Mrs. C. A. Coffin. The carnation classes were divided between T. D. M. Strachan (A. Andrews, Supt.) and Mrs. F. W. Woolworth (James Churchill, Supt.). Mrs. H. L. Pratt won the Stumpp & Walter Cup with a fine collection of vegetables, twelve varieties. The fruit section also went to Mrs. Harold I. Pratt. On table decorations Mrs. Andrew Fletcher (Ed Harris, Supt.) won the first prize, a silver cup donated by Mrs. H. L. Pratt; 2nd, Mrs. A. C. Bedford (William Milstead, Supt.); 3rd, Mrs. Harold I. Pratt; 4th, Mrs. J. P. Morgan.

A. S. Cooje, Cor. Sec.

DISCOVERY

Autumn is a time of revelations. If, in the early spring, the tree is garbed overnight in a mantle of soft green, may not the autumn gale which strips that same tree of its dress, grown bronzed and copper colored, bring a new revelation? The foliage is only a seasonal gown; it adorns the tree, but it is not the tree. The autumn frosts and winds do their work in discovering for us the delicate tracery of bough, branch and tiny twig. Let there be many trees, as in a wood, and we have a marvelous lattice work through which wonderful things may be seen.

All summer the abundant foliage and thick underbrush, encouraged the belief in a forest without bounds; but one morning after a night of torrential rains followed by strong winds, we looked out upon our wood, and the trees were bare and denuded trees

The greenhouse pictured is 48 feet wide and 33 feet long.

The Most Greenhouse for the Least Money

BY saying *the least money*, we mean the least consistent with undiminished efficiency and assured attractiveness. Just for identification sake, we call it the Number Two House.

In this Number Two Greenhouse with its straight eave, we have simplified all parts of it so that the completed building, including the foundation, will cost you from 20% to 25% less than our curved eave one. If that sounds interesting, you may incline to send for a new booklet just published, called "The Most Greenhouse for the Least Money."

Seedsman and Florists

35 and 37 Cortlandt St., NEW YORK CITY

we saw the picturesque relic of an old block house; the lichen-covered beams a silent witness to sterner days when pioneers hewed a path for civilization. Through the screen of twisted oaks and straight pines a cotton field; the sunlight gently touching each bursting pod; beyond, a low-built farmhouse, perched high upon a neighboring hill. All these lay hidden in, and beyond the verdant trees. They are revealed to us by autumn's breath.

The sunbeams, now unhindered, sweep the woodland paths, turning the wet leaves to burnished gold, over which the grey squirrels scurry as they cache their winter store of nuts.

So autumn, like every season of the year, is an opening, not a closing, door; a new beginning, not an end.—C. S. M.

STATEMENT OF THE OWNERSHIP, MAN-AGREEMENT, CIRCULATION, ETC., required by the Act of Congress of August 24, 1912, of "Gardeners' Chronicle of America," published monthly at New York, N. Y., October 1, 1922. State of New Jersey, County of Union

Before me, a notary public in and for the State and county aforesaid, personally appeared M. C. Ebel, who, having been duly sworn according to law, deposes and says that he is the editor of the "Gardeners' Chronicle of America" and that the following is to the best of his knowledge and belief a true statement of the ownership, management (and, if a daily paper, the circulation), etc., of the aforesaid publication for the date shown in the above caption, required by the Act of August 24, 1912, embodied in section 443, Postal Laws and Regulations, printed on the reverse of this form, to wit:

1. That the names and addresses of the publisher, managing editor, and business manager are: Publisher, The Chronicle Press, Inc., 286 Fifth Ave., New York, N. Y. Editor, M. C. Ebel, 286 Fifth Ave., New York. Managing Editor, M. C. Ebel, 286 Fifth Ave., New York. Business Manager, D. Ebel, 286 Fifth Ave., New York.

2. That the owners are (give names and addresses of individual owners, or, if a corporation, give its name and the names and address of stockholders owning or holding 1 per cent, or more of the total amount of stock).

The Chronicle Press, Inc., 286 Fifth Ave., New York, N. Y. M. C. Ebel, Summit, N. J. M. E. Burniston and J. A. Burniston, both of Summit, N. J. S. Warendorff, 325 Fifth Ave., N. Y. Chas. H. Totty, Madison, N. J. A. Bauer, Deal, N. J. J. Barnett, Sewickley, Pa.

3. That the known bondholders, mortgagees, and other security holders owning or holding 1 per cent, or more of total amount of bonds, mortgages, or other securities, are: (If there are none, so state.) There are no bondholders, mortgagees or other security holders.

4. That the two paragraphs next above, giving the names of the owners, stockholders, and security holders, if any, contain not only the owners, stockholders and security holders as they appear upon the books of the company, but also, in cases where the stockholder or security holder appears upon the books of the company as trustee or in any other fiduciary relation, the name of the person or corporation for whom such trustee is acting, is given; also that the said two paragraphs contain statements embracing affiant's knowledge and belief as to the circumstances and conditions under which stockholders and security holders who do not appear upon the books of the company as trustees, hold stock and securities in a capacity other than that of a bona fide owner; and this affiant has no

Those Giant Dahlia Zinnias in Separate Colors

Largest and showiest of Dahlia Zinnias, with long broad, velvety petals, overlapping each other. Each stem a marvelous blending of pastel color shades too subtle to describe, yet each markedly different and true to color make these magnificent flowers the true aristocrat of the Zinnias. There are twelve colors.
Exquisite—Color light rose with center a deep rose (*Tyrus Rose). **Golden Monarch**—Largest and best of the red shades. Flowers often eight inches in diameter. **Giant Attraction**—A distinct shade of brick red (*Spectrum Red), forming an immense ball of color in full bloom. **Scarlet Flame**—A beautiful, bright scarlet, with a delightful blending of orange throughout the petals. **Meteor**—A rich, glowing deep red (*Spinal Red) and the darkest of all of the red shades. **Oriole**—An immense orange and gold border changing slightly as it flowers but at all times worthy of its beautiful name. **Sunrise**—A combination of pleasing apricot shades, changing to full as it ages. **Dream**—Fine, deep, lavender, turning to purple (*Mallow Purple). **Polar Bear**—Very large and pure white. True Dahlia form. **Buttercup**—An immense rich, creamy yellow bloom. A splendid accent to any collection of Zinnias. **Golden State**—A very rich orange yellow (*Cadmium). Yellow in the bud, turning to an attractive orange when in full bloom. **Canary Bird**—A delicate shade of primrose—very large and holds its color well until out of bloom.

This collection—1 packet each, 12 colors—\$5.00. Or, if you prefer, any single color, 75c. the packet.

Things and Thoughts of the Garden

WILLIAM N. CRAIG

THE continuous stream of seed catalogues at this season concentrates our thoughts once more on the garden and what we shall plant the coming season. The first and most sumptuous of these catalogues came to hand as nearly as December 10 from Sutton and Sons, England. Our English friends send out their seed lists much earlier than we do, because Spring over there starts while the ground here is still buried in ice and snow, in fact, it is only occasionally that they have a Winter sufficiently severe to delay outdoor seed sowing until March. There is much pleasure to be derived from the perusal of the incoming seed lists on cold Winter days when a mantle of white covers terra firma and the thermometer flirts with the zero mark. We are always specially interested in the novelty lists. The descriptions are often fanciful and thrilling, and we feel impelled to try a packet of one or two of the new things catalogued. This is an excellent idea, for we cannot afford to be too conservative in the garden if we want to make it attractive and appealing. Harmonious blendings of colors in the flower garden are unquestionably the first consideration, but if one can work in a few novelties, they seem to give an added spice. Only a limited proportion of the new things come true to their laudatory descriptions, but if one or two make good, surely we are amply repaid for trying them.

The omnipresent scarlet salvias, red geraniums, yellow and red cannas, and other subjects which form the principal staples of the average florist who handles bedding plants, are tabooed in many gardens, and rightly so, but that they still have a place and a warm place in the hearts of many, none can deny. To many, a mass of scarlet salvias, cannas, or geraniums, is one of the finest possible floral pictures and they would much prefer them to a garden of perennials and annuals, painstakingly planted and religiously culled as to colors so that there will be no floral conflicts. We may pity those who do not view things as we do, but let us be glad that they love flowers at all, see beauty, and find enjoyment in them. Some day they may try other plants and produce more æsthetic effects. I can see a steady advance among amateurs, and in increasing number find mixed plantings in borders of bulbs, perennials, and annuals, vastly more satisfying than the former stereotyped masses of such subjects as we have named.

In purchasing flower seeds, I would commend an in-

creased use of beautiful single Chinese asters. The variety, Southcote Beauty, obtainable in a number of colors is lovely. Seed may be sown from the end of February until the middle of June if a constant succession of blooms is wanted. The flowers are large, averaging four inches in diameter, and are carried on stems twelve to twenty-four inches long. The colors include mauve, pink, white, scarlet, coppery rose, and crimson scarlet. If possible, asters should have a change of soil, which will help to eliminate stem rot and yellow. The black beetle which loves to devour the opening flowers, can be controlled by a spraying of Paris Green in water, an ounce will suffice for ten to twelve gallons, and if a little lime is added, the danger of burning will be prevented. Thus weakly applied, the poison will finish the beetle and not discolor the flowers noticeably.

* * * * *

Anchusa, Dropmore and Opal, are well known perennials with somewhat coarse foliage. The color, however, is excellent in the garden. Too few garden lovers sow the pretty annual Anchusa which has forget-me-not like flowers and small foliage, which resembles a glorified myosotis. It flowers in eight to ten weeks. From seed sown as late as the end of June, it will make a lovely showing of bloom from September onwards. This Anchusa can be sown where it is to flower, or transplanted. Those who have not grown the old *Salvia sclarea*, (Clary) an old-fashioned mauve-colored variety, should try it and, of course, none should overlook *Salvia farinacea* with lavender flowers, a good flower and most effective in the garden. It is also excellent for cutting. For those wanting a free flowering blue annual of moderate growth, I would recommend the blue shade of *Phlox Drummondii*, and in mountain and shore resorts, *Nemesia*, Blue Gem, succeeds very well, as does the upright flowering *Lobelia tenuior*. *Browallia speciosa major* blooms a long time in the garden and its large, bright blue flowers are most effective. It furthermore makes a fine basket plant. There is no annual suitable for border purposes which is a more persistent bloomer than *Torenia Fournieri grandiflora* with violet, blue, and white flowers.

* * * * *

Ipomœa, Heavenly Blue, is an unusual sky blue morning glory, which is more delicate than the ordinary morning glories, or convolvuli as they are still often called. It must be started in a greenhouse and not planted out until we have really warm and settled weather. It also makes a lovely plant for greenhouse or conservatory

JAN 20 10 2

decorations, succeeding specially well in a large pot or tub, and trained on a trellis. There is no better quick, tender climbing perennial today than the purple and white forms of *Cobæa scandens*, when it is desired to cover a fence, pillar, or trellis thickly and quickly. Speaking of fences and rough stone walls, the ornamental gourds come in finely. They are quite numerous and their ripened fruits are most attractive. At a vegetable collection, a collection of them at once attracts attention; especially good are the apple shaped, bottle shaped, orange, egg, pear, Hercules Club, calabash, dish cloth, and Bishop's mitre varieties.

There are about the usual number of vegetable novelties and at least a portion of them should be tried out. The yellow sweet corns are now rapidly pushing the white varieties into second place. Golden Giant still seems to be the best, but a whole lot of other good yellows are now available. There is certainly a sweetness to the yellow varieties we cannot get in Crosby, Stowell's Evergreen, Potter's Excelsior, Country Gentleman, and other good whites, although the larger varieties will remain popular for canning purposes. Peas are the crop which demand early planting, and there is no better all round early sort today than Sutton's Excelsior, while for those who can give a tall, lusty grower the necessary supports, Alderman still stands without a peer as a main and late crop variety. World's Record is very good as a second early and Improved Gladstone is hard to beat as a late variety. It is pleasing to note an increased interest in Finocchio or Florence Fennel excellent as a salad and very good cooked or served naturally like celery. This vegetable, if sown too early, will run to seed; early July is a suitable planting time.

Why not plant a little patch of sweet and pot herbs this year? Nothing can be more interesting, and many in addition to their fragrance, have culinary, medicinal and other uses. Out of the large number of varieties, lavender and rosemary should be started in a frame or greenhouse. Lavender with a little protection has for years withstood temperatures far below zero, but rosemary is more tender and should be wintered indoors. It makes a nice pot plant. Of the other perennial herbs, some of the more useful and easily grown are: Mint, pennyroyal, lovage, horehound, balm, sage, broad leaved sorrel, thyme, and angelica, the last named is a very lusty grower and attains a height of eight feet when in seed, and presents a semi-tropical effect. Tarragon while hardy, will sometimes die out, and it is a good plan to winter a root or two in a frame. Some of the varieties which are annuals or tender perennials are: Sweet basil, Summer savory, Winter savory, sweet marjoram, pot marjoram, dill chamomile, coriander, anise, and caraway. There is no need to sow any of the annuals outdoors until May, but lavender and rosemary may be sown under glass now.

On mild days during the Winter, the spraying of all fruit trees as well as deciduous ornamental shrubs and the species of hardy roses should be done. We should not leave this very necessary work until Spring. Goodness knows we have more than we can properly accomplish at that time. Such soluble oils as Scalecide are best for the amateur—the big growers are divided between oils and liquid lime sulphur. One or two oil preparations have been put on the market which have damaged trees, but I have never known Scalecide at one to twenty to do so. A year ago I had occasion to visit a private estate and

was asked to explain why a house of peaches and nectarines had failed to break. It did not take long to locate the trouble—one of these soluble oils had been applied at the fifty-fifty rate! I need hardly say that no amount of syringing would make these trees break, as they were practically killed outright. We have learned to fear the San Jose scale less and less as we have learned how to spray, and have better fruits and cleaner shrubs as a result of these dormant Winter treatments. By all means, if you have not yet sprayed, do so on a mild day when the sun shines, and you will not only kill the various scales, but many eggs of other insect pests.

A query often repeated is "How can poultry manure be used to the best advantage?" To begin with, the scrapings from the roosts should be removed each week, dusted with acid phosphate and placed in barrels on the floor of a shed where they will NOT be exposed to the elements. Acid phosphate is an inexpensive fertilizer, is non-odorous, and pleasant to handle. It holds the ammonia in the manure and for that reason, is much used on the floor of cow barns where the manure and urinal constituents drop, thus preventing great wastes in ammonia. It should be spread over the dropping boards when they are cleaned off and a little more added when the manure is placed in a pile or barrel. The wrong way to keep poultry manure is outdoors where it will steam if in heaps all Winter and waste the major part of its strength. It is a forceful manure, and rather than dig it or spade it into the soil, it will be found especially valuable as a top-dressing to stimulate plants when growing. Peas, leeks, onions, cabbages, cauliflower, egg plants, squash, celery, roses, gladioli, cannas, asters, dahlias, peonies, and larkspurs are a few of the plants which respond readily to a topdressing of it, which should be always worked lightly into the soil with a hoe, rake, or cultivator.

The shortest days have passed and they are now appreciably lengthening. The cold strengthens but the sun's rays will ere long melt the snows on hillsides and in warm secluded spots we shall soon be looking for the first snow-drops, to be followed a little later by crocuses, winter aconites, chionodoxa, and scillas, a group of simple, innocent, inoffensive bulbs, never known to bring in any dangerous insect pests or diseases and not being successfully produced in America at all, yet with the exception of crocus denied to us by our all powerful Federal Horticultural Board which contains alas, not one horticulturist. But a late hearing somewhat encourages us in supposing that facts adduced at a recent hearing may have so far punctured the anatomies of these August protectors of our plants and nurserymen that they may relent and allow us to import some of the denied bulbs "under suitable safeguards," for a limited period. It seems queer that it should be safe and necessary for one firm to import thousands of *dicentra spectabilis* and for the issuance of special permits for great numbers of such extremely rare plants as Norway maples for nurserymen supporting the notorious Quarantine No. 37; yet that amateurs who have really made horticulture here what it is, should have been denied the early little Spring bulbs named except they furnished bonds and went through an endless and entirely ridiculous amount of red tape. And it is encouraging in some measure to those who steadily condemned the embargo and demanded needful modification in it, that the Federal Horticultural Tariff Board (as it would most properly be called) has at last been compelled to make a concession to the despised amateurs.

The Fern Garden

ANNA B. FREEDLEY

It seems strange to me that so little is written about our native ferns. We have numerous articles devoted to the perennial or annual and even to the wild flower garden. In fact modern literature is almost over supplied with such information and I often wonder why the ferns have been so neglected. They are most abundant throughout the northeastern United States, especially in the mountains of New England. Perhaps their abundance is one reason, for along every roadside and woodland path

The Interrupted Fern

and in every meadow and pasture they are always to be found. Something more showy and harder to obtain, some new and large variety of flower, seems to attract the attention of the garden makers of to-day.

My fern garden is a source of much pleasure and interest to me with its cool greenness all through the hot summer days and even after a heavy frost has touched all but the evergreen varieties, for these still stand up, their glossy fronds making a pleasing contrast with the falling Autumn leaves, so gay in color.

There is infinite variety in the ferns. The foliage is of many different shapes and shades. The fronds are graceful and arching, stiff and upright, or even low and creeping; some are finely cut giving a dainty and feathery appearance, others are broad and entire, giving a more solid and blade-like effect. I have found them all hardy, easy to transplant, and most satisfactory under cultivation.

They belong to the Cryptogams, being flowerless plants and produce spores which take the place of seed. It takes two generations to make a new fern. From the ripened spore which has fallen to the ground rises the prothallium, a thin heart-shaped plant about a quarter of an inch across, or sometimes a little larger, which is attached to the ground by small roots. This very tiny plant is short-lived, living only a few days and bears the antheridia

and archegonia, which correspond to the stamens and pistils of the flowering plants, and their union results in the new fern, which again in its turn bears the spores. Most of the ferns increase also by underground stems which send up buds and in this way new plants are formed, for they may be detached from the parent and transplanted. My ferns have increased rapidly. Every year I find new shoots and I have several times found it necessary to thin out a clump or move a plant which was being crowded by its neighbor, perhaps a larger or more vigorous type.

A fern garden in a shady corner of the garden or beside the porch is a source of daily delight and a study of these interesting and beautiful plants in their many forms and varieties will amply repay the slight trouble that they may give, for they make an almost troubleless garden by their hardiness and ability to withstand the crowding of the ever-present weed. Indeed they thrive better than the weeds! I think this is because in their native haunts they are always surrounded by other plants and their roots have become accustomed to and strengthened by a continual struggle with the large roots of trees and bushes and tough perennial weeds. They seem to be always crowded and yet always to be holding their own. The little weeds which pop up in our cultivated gardens must seem very insignificant compared to the wild growths which the ferns encounter in woods and hilly pastures. Often while digging up specimens to bring home I have had more trouble with neighboring roots than with those which I desired to procure.

The first thing to consider in planning a garden of any kind is the location. Ferns require shade and as much coolness and moisture as can be obtained to carry them through the hot part of the season. A northern or northeasterly exposure is no doubt the best. My garden faces the southwest, which at first will seem a very poor spot indeed, but two large elms and a linden shade it nearly all day and the sunlight filtering through the leaves gives the added charm of changing light and shadow to this all green garden.

The soil condition should be considered next. This should be mixed as far as possible to resemble the soil in which we find them growing. Most varieties grow in woods where it is not unusual to find them in pure leaf mold and leaves in different stages of decay, the upper roots running like little silver ribbons between the flat surfaces in search of nourishment, while the larger and older ones penetrate to the soft rich soil beneath, which is composed almost entirely of decomposed leaves fallen in past Autumns. Leaf mold, then, must be added to the chosen plot of ground in large quantities. A mulch of well-rotted manure is beneficial, but not at all necessary. For Winter covering plenty of leaves is all that is required as that is the only protection they receive in the woods. This also keeps the soil in good condition as some leaf mold is added each year.

A few hours walk through the woods with trowel and basket will yield many specimens with which to start the garden. If anxious for an immediate effect with some fairly large plants for background and accent, a spade must be used in order to procure as much root as possible. Be sure to give plenty of water at time of transplanting and, if it be a hot day or during a dry spell, continue watering the plants for several evenings following or until the fern becomes accustomed to its new situation.

Some ferns grow along roadsides and in the fields exposed to the full sunshine. These seem of a tougher, thicker texture, no doubt developed as far as possible to retain all the moisture they can obtain. They take very kindly to a cool cultivated spot and seem to appreciate it by developing foliage of a soft rich green, losing the yellow tint the sun gives to them. The wood loving ferns are the daintiest and most beautiful, being more feathery in appearance and of a finer texture.

The Interrupted Fern (*Osmund Claytoniana*) and the Cinnamon Fern (*Osmunda cinnamomea*) are two of the most satisfactory large ferns, growing to a height of from four to five feet. They have long graceful fronds coming from the crown in a circle and giving the plant a vase-like shape.

The Cinnamon Fern is a medium green, with rather finely cut edges and is unusually dainty in appearance for such a large variety. The spores are most interesting. They appear in June on stems rising from the center and hang like minute bunches of dry and crinkled grapes. They are a lovely soft brown and from this fact the fern takes its name. These fertile stalks disappear later in the Summer, but the sterile or leafy fronds stay green and fresh until late in the season.

The Interrupted Fern is quite different. The fronds are lighter green and not being so finely cut along the edge, give a more substantial effect. The spores are the same soft brown, but are borne midway up the leafy frond interrupting the pinnæ which are opposite and arranged in even ranks. These spores hang in little clusters similar to those of the Cinnamon Fern. They are very ornamental and remain on the stalk all the season making an interesting note of color in this green garden.

Both of these ferns have a large tough rootstock which makes them a little more difficult to dig up than some of the smaller varieties, but they are very hardy and even if the root becomes broken, which is almost sure to happen, they recover rapidly. I have a lovely specimen of the Interrupted Fern in my garden which gave me a great deal of trouble when digging as this large root had worked its way between two rocks. After trying in vain for some time to get a large portion of the root, I broke it off and carried it home, only to see it droop most forlornly. I planted it carefully and watered it thoroughly, but the next day it still drooped and when one frond turned yellow, I was sure I would lose it. However, I continued to give it plenty of water and it responded by gradually cheering up and is now one of my most attractive plants. It has proved its hardiness and willingness to be transplanted by doing well under cultivation.

These two larger varieties are especially useful as accents by steps or in the bays and promontories of the garden design.

The medium-sized ferns which we will consider are the Spinulose Wood Fern, the Evergreen Wood Fern, the Long Beech Fern, the Christmas Fern and the Sensitive Fern.

The Spinulose Wood Fern (*Aspidium spinulosum*) is one of the most beautiful of the ferns. It is vase-shaped and grows to be one foot to one foot and a half high and is very finely cut, looking like lace. It reminds me of the fine mesh we see in the lace collars which the old Dutch gentlemen wore while sitting for their portraits. It is a good medium green and makes a very attractive mass effect for filling in the middle portions of the design. The sterile and fertile fronds are similar. The spores are round, pale yellow and are borne on the under side of the pinnæ. They are inconspicuous and not often seen except by those who turn the leaf over in search for them.

The Evergreen Wood Fern (*Aspidium marginale*) is

very similar in size and shape, but in texture is much heavier. The color is deeper green, with a dull almost leathery finish and the new fronds are a bright Spring green, making a decided contrast with the older leaves. The edges of the pinnæ are rather coarsely incised and the general appearance of the fern is that of stability. The leaves stay green all Winter under the snow. The spores are deep brown, disk-like and prominent, borne on the under side of the pinnæ at the extreme edge. The sterile and fertile fronds are alike in shape and color, the spores not visible when looking down upon the plant.

The Long Beech Fern (*Phegopteris polypodioides*) is a most attractive little plant, being not quite as tall as the two varieties just described. It is rarely over one foot in height. It possesses a charm which the other ferns do not have and it should have a place in every garden. Its cheerful and almost pert appearance attracts the attention of every visitor. Its expression is the same as we find in the face of the pansy,—full of good nature and happiness. The fronds are medium green, of good texture and taper to a sharp point. The lower pair of pinnæ turn upward, almost set at right angles to the main stem. It is exceedingly interesting and makes such a pleasing contrast with the more graceful and arching fronds of some of the other varieties, that it fully repays a longer search in meadow and woodland, for it is not as common as those mentioned above. It is also very hardy and satisfactory under cultivation.

The Christmas Fern (*Aspidium acrostichoides*) is familiar to everyone with its long narrow fronds of deep glossy green, very sharply pointed, which sometimes droop gracefully and sometimes stand erect in an almost defensive attitude. This fern is evergreen and substantial. It is good for foreground or middle distance and is especially distinctive used as a small accent. The fertile fronds are quite noticeable, as the tip is constricted and shriveled. The spores are borne on the under side of this tip in crowded groups and are of a rich brown color. Each pinnæ is armed with small sharp bristles and the stem has small tufts of brown down on either side.

The Sensitive Fern, (*Onoclea sensibilis*) is so called because the young leaves which first appear in Spring droop quickly and are tender. It is not really sensitive, but quite hardy. It is found along roadsides exposed to strong sunlight or along woodland paths. The specimens that are growing in sunny situations have a distinct yellow tone, while those in the shade are darker, greener, and more thrifty. The leaves are deeply lobed, having an entire edge which gives the plant a very different appearance from any of the other ferns. There is also a form with undulating edges. The spores are borne on their own stems and are quite conspicuous. This fern is valuable for obtaining contrast on account of its distinctive foliage.

One of the smallest ferns is the Common Polypody (*Polypodium vulgare*), sometimes called Snake Fern. It is seldom over six inches in height. It is found through the woods and along the banks of mountain streams, covering rocks and boulders like a carpet and growing in tiny crevices where there is hardly a bit of earth. It is, therefore, valuable for rock work and to place between flag-stones. The fronds are slender, deep green and of a dull leathery texture. They are evergreen and resemble the Christmas Fern in shape, but are not glossy, do not have the small bristles on the leaflets and are much smaller. The spores are borne on the under side of the leaf at the tip, and are deep yellow and very close together.

The Maidenhair Fern (*Adiantum pedatum*), so well known and so well loved by all, hardly needs to be

(Continued on page 8)

Japanese Morning-Glories

SOME of our most popular flowers have either originated, or been much improved in Japan. The morning-glory, called by the Japanese "asagao," is one of the plants to which they have paid particular attention. Although brought to Japan about the sixth century by priests and scholars who had gone to China to study the Buddhist religion, it was not until about the seventeenth century that the morning-glory received any special attention. Flowers then began to be produced in innumerable shades and combinations of colors and the size was considerably increased. About 1830 the "asagao" again became popular, growers vying with each other in producing new varieties, and a single seed might command a price of twenty-five dollars or more. Interest gradually declined, however, and the art of cultivating this

(Courtesy of Missouri Botanic Garden Bulletin)
Japanese Morning-Glory Blossom

plant was retained only by a few priests. About 1895 interest was again revived, "asagao clubs" were formed, and famous morning-glory gardens were established in Tokyo. Poetic names, such as frozen moonlight, foam of the sea, dragon's spume, full moon, were bestowed upon the finest blossoms; artists used them in paintings and designs; and numerous poems were written on them and to them. In fact, the morning-glory became a national cult even more than the chrysanthemum had ever been. The Japanese growers went to every possible extreme in changing the shape and color of the flowers. Not being satisfied with this achievement, they devoted their attention to producing the greatest variety of odd-shaped leaves, and in their quest for eccentricities produced flat stems which have the appearance of a wide-ribbed ribbon, as if many stems were laid side by side and then merged into one. The "asagao" was not only popular because of the wide range in size and color of the flowers but because the plants could be grown as "dwarfs."

Attempts have repeatedly been made to show these Japanese morning-glories at the Garden, but all the seed obtained either failed to germinate or produced the common types of this country. In the early part of this year,

however, seed of these dwarf morning-glories were obtained from Japan through Mr. Takashi Matsumoto, a former student in the Shaw School of Botany. This seed was divided, one-half being sown the middle of February and the second half the beginning of June. The seeds of the first lot germinated very unevenly, but by cutting a notch in those seeds that failed to show signs of life in two weeks the majority were made to develop. Most of these plants were extremely dwarf, sometimes being less than a foot high with not more than half a dozen leaves. These tiny plants produced the most gorgeously colored flowers, often four to five inches in diameter. Seeds from these flowers did not set freely, but the few that were secured were planted as soon as mature. In the second generation, however, instead of dwarf specimens, plants were produced that climbed fifteen feet and more. The size of the flowers was not diminished, some of the pink varieties measuring six inches in width. Still more interesting and peculiar is the fact that the second planting of the original lot of seed received from Japan, which was made the first week in June, instead of producing dwarf plants, sent out long vines so that the bamboo

Japanese Morning-Glory Plant

trellises, described in the Japanese instructions, had to be employed to train them. In order that germination might be hastened every seed of this second lot was cut, and practically all germinated within forty-eight hours.

The following directions, printed just as translated by Mrs. Matsumoto, were received with the seeds:

"CULTURE OF THE MORNING-GLORY"

"In order to meet the requirements for growing the morning-glory, the soil must be superior in two respects, drainage and fertility. Under no circumstances use heavy clay.

"The time of sowing is entirely governed by the climate, and it is very important that the growers should be acquainted with their local climatic conditions before growing these special plants. For the vicinity of Tokyo the sowing season generally starts in the middle of May or a little earlier. In general, the plants grow much better in warm places; therefore, the growers should not

sow the seeds until they feel quite sure that warm weather has come to stay, and there is no fear of frost injury.

"There are two types of seed-beds. The one is by sowing the seeds in a framed bed, and the other is by sowing them in a pot.

"I. Framed beds. For this purpose the bed should be well ventilated and sunny. It is very convenient to make the beds about three feet in width, but their length may be of any desired extent. Simple culture frames of usual type are employed, except that no glass cover is used, and their height is usually about five inches.

"Place the frames where the seeds are to be sown, and fill them with well-drained soil (about three to four inches deep) by sifting. Smooth the surface and sow the seeds on the bed and cover the surface with sifted soil (about $\frac{1}{4}$ inch in thickness), and sprinkle water, using only very small streams. It is a good practice to place a thin layer of straw upon it, and allow it to remain until the young plants appear at the surface of the bed. For the purpose of forcing, it is desirable to peel a tiny bit of the seed-coats before sowing. The right place for peeling is near a sunken spot where the germination takes place. Under a favorable condition the seeds begin to germinate in three to four days. When the casing soil is too shallow, the cotyledons will sometimes appear covered by the seed-coat. In such cases those coats should not be taken away when they are dry, as it often causes some injury to the cotyledons.

"II. Potted beds. In potted beds culture practically a similar method can be applied, with the exception that pots instead of frames are used.

"Transplanting: A seedling should be transplanted twice; first, from the seed beds, either framed or potted, to a small pot (about $2\frac{1}{2}$ inches in diameter)—the purpose of the first transplanting is to prevent unnecessary growth of the plants; second, remove it to a larger pot, usually 5 to 6 inches in diameter. The first transplanting begins immediately after the cotyledons have opened. If the plants are left in the beds too long, it is very difficult to transplant them without giving any injury to the roots and cotyledons. As a matter of fact, it is very much desired by growers to keep the cotyledons on the plants until the flowering season; therefore, the growers should take much pains to keep them as long as possible.

"Fertilizers: Rape cake is generally used as a fertilizer, which is frequently applied to the soil in the form of powder, but mostly in liquid, which is thoroughly fermented. Chili saltpeter, ammonium sulphate, or potassium sulphate, etc., is frequently used as a substitute of the first named.

"Watering: The seed-beds should be always moistened until the young plants appear on the ground. After transplanting it is a usual practice to water twice a day, once in the morning and again in the day time. It is desirable to use warm water for the day-time watering.

"Supports: When the plants grow up to 6 or 7 inches high, it is absolutely necessary to furnish some supports. For this purpose bamboos or reeds are generally used. The supports are arranged in various ways, of which the following two are very common:

"A, 'Andon' type (Lantern type). B, 'Boshi' type (Hat type).

"A. Andon type. Height of the supports is dependent upon the individual tastes. Erect four or five bamboos or reeds along the inside of the pots, and connect them with three rings of bamboo.

"B. Boshi type. A piece of bamboo is bended down to the soil, thus making an arch-like form, which is then crossed with two pieces of bamboo. This type of support is especially recommended for some special varieties which have hard stems.

"For the morning-glory culture it is a matter of most importance to help the stems of the plants to climb up the supports. The most desirable time for winding the stem is during day-time, as it is very tender, while in the morning or evening it is very brittle and could not be wound without causing injury to the plants. The stems naturally twine the supports from left to right, therefore it should be arranged in that way, otherwise the stem may refuse to twine the supports.

"Try to wind the stem in the basal ring, and when it returns to the starting point, then lead it along an erect bamboo to the second ring, and wind the stem in the same way as stated above. It is desirable to check the growth of the plants when their stem encircles the second ring, and never let it grow further up to the third ring.

"Flowers usually bloom early in the morning and may wither soon when they are exposed to strong sunshine. The withered flowers should be picked at about ten o'clock every morning. For the purpose of getting seeds for next year, however, it is without saying to leave the withered flowers on the plants."—*Missouri Botanical Garden Bulletin*.

THE FERN GARDEN

(Continued from page 6)

described. Its dainty curving stem with the little triangular leaflets on either side is very lovely indeed. The stem is slender, smooth and glossy, and slightly brittle. In books it is generally said to be black, but in reality it is far from black, having many tones varying with the changing light, from plum to bronze. I have often been reminded of the stem of the Maidenhair while paring a large and well-ripened eggplant, for they possess many of the same shades. The spores are small, light brown and borne on the under edge of the leaflet, which turns back and partly encloses them in little pockets and gives a slightly puckered effect to the edge of the leaflet. This fern in spite of its very delicate appearance is quite hardy and I have several clumps which have increased from year to year. Thinking it very tender, my first clump was transplanted with great care on a dull day with drizzling rain, for fear it might become wilted. Another clump was brought in from the woods on a bright sunny day in mid-July. It was carefully carried home in a basket and planted with plenty of water as soon as possible after digging. They did not droop and seemed to take readily to the new place. About two weeks later I was much surprised to discover six new fronds starting up from one root and four from another, which developed into fluffy masses of foliage and remained so until the end of the Summer. So I have found this fragile looking fern to be one of the most hardy and satisfactory in my collection. It is most decorative and does well in middle distance or for the border and is especially effective in a large mass. I think the delicacy of the foliage is shown to greatest advantage against a wall or where it can droop gracefully over flagging or pathway, for then the shadows cast a fine tracery and add a fascination to this already fascinating little plant.

There are, of course, many other varieties of ferns, all lovely and most interesting to study and discover in their native haunts, far too many to be described here. I have only mentioned those which I have in my garden and with which I feel well acquainted. I can vouch for their beauty and their hardiness. The ferns should surely have a place on every estate, no matter how pretentious, and on every cottage lawn, no matter how humble, for they adapt themselves to all surroundings. They are always suitable and in good taste adding a charm and grace to the garden that no other plant can give.

Wistarias and Their Training

EVEN those who have least love for Japanese gardens and Japanese gardening must admire the Wistaria. Like the Japanese Cherries it is "everybody's tree," and yet how many houses does one see smothered in various, more or less effective, climbing plants, but destitute of Wistaria? Why is this? For a house with any pretensions to architectural interest the Wistarias are surely the best of all climbing plants. (Climbing plants they are, though they cannot climb on a flat surface, needing something comparatively thin round which to twist the young wood.) The growth of both the commonly-grown species—the so-called Japanese, *multijuga*, and the Chinese, *chinensis*—is vigorous without being overpowering, so that they may be readily trained to adorn rather than to smother the front of the building against which they are planted.

The "Japanese" Wistaria, as we know it, has doubtless been considerably improved by the Japanese florists, but

The superintendent's cottage at "Lyndhurst," the estate of Mrs. Finley Shepard, Tarrytown, N. Y., with the wistarias in bloom.

it is really a native of North China and probably not indigenous to Japan. It is magnificent for training over tall pergolas or on an elevated trellis. For walls it is really less suitable than *W. chinensis*, though by training main laterals horizontally and a sufficient distance apart, it may be shown to advantage there also.

The association of various habited "furnishing" plants to architecture receives much less attention than it should. A bald uninteresting expanse of walls is caused by want of appropriate detail. If a cornice would have filled the bill in the original design, the bad effect can be at least greatly mitigated by training a Wistaria horizontally to replace the missing element. Similarly, living pilasters of *Crataegus*, for example, will provide upright features where desirable.

If the wood of the past year is reduced each Winter to three or four eyes, the Wistaria will make a satisfactory self-supporting bush. Indeed, plants which have been stunted in pots in the nursery often retain the bushy habit. If they are wanted to climb, care should be taken to purchase healthy young trees with an abundance of young wood. The pruning of a climbing Wistaria is (or should be), similar to that of a trained pear tree. Laterals are taken off where required and allowed to extend reasonably each year until their allotted space is filled. The sub-laterals are Summer pruned to ten or a dozen leaves—if this is not done there will be yards of thin growth tangled all together—and in Winter spurred back to the flowering

wood. With plants trained on wires to give the "floral bell tent" effect so well known to visitors to Kew Gardens, the training may be more informal, but the same principles will apply.

The common form of the Chinese Wistaria has flowers of a delightful mauve tone, so distinct as to be a commonly used color shade. The "Japanese" species is, in commerce, a much more variable plant, but if one can but obtain them, its best forms are darker and even more desirable as regards coloring than the Chinese. The length of the racemes in this species is extraordinary. The rosy form—*rosea*, is well known, but less beautiful than the mauve purple ones and there is a pure variety which is rather shorter in the raceme, though still long, and later to flower. The white form of the Chinese species is, strangely enough, earlier to flower than the typical plant. The general experience is that it is less free to flower than the typical mauve.

Like the Grape Vine the Wistaria develops quite a trunk and butt with age. A diameter of more than 18 inches is not uncommon for the trunk of an old specimen. The Wistaria, fortunately, is comparatively long lived. Its introduction to English gardens dates back just over a century (1816), and some specimens now in existence must be close upon a century old. The oldest specimens, however, almost invariably show signs of decrepitude with hollow trunk and diminishing foliage, so that the effective age of the plant may be placed at from eighty to a hundred years.

Bush Wistarias are, as a rule, planted to associate with water which, of course, redoubles their charm by reflecting the glorious trails of blossom. One feels that had these beautiful woody climbers been known in Tudor days, many of the pleached avenues of Lime and such like would have been carried out in Wistaria. There really seems no reason, therefore, why those with old gardens (or with gardens to an old house) should not plant Wistaria to be trained in this manner. They would ultimately become almost, if not quite, strong enough to stand alone. It is not quite evident why, when reconstructing an old garden, we should be bound by the limitations which handicapped our forefathers. Surely it is better to build upon the past with whatever of old or recent introduction will best serve the end in view! The Wistaria is assuredly an old-fashioned flower. Even though it has been cultivated for a mere century in Britain, it has been grown no doubt by the gardeners of Japan since long before Tudor times and it has that peculiar sophistication characteristic of plants long in cultivation.

As previously stated, both the Wistarias commonly cultivated in this country are of Chinese origin. Though sufficiently distinct, they are obviously closely related. There are, however, other species in existence of which two at least are Japanese. Of these the only one of which much is known, *W. japonica*, was introduced as long ago as 1878. Compared with *chinensis* or *multijuga*, this species is a pigmy with numerous small white flowers in racemes 6 inches to 12 inches. It is said to provide a wonderful spectacle when smothering a large bush or small tree, but is seldom seen in cultivation in this country.

The American species, *W. frutescens*, bears its flowers in short terminal racemes, often held erect. The flowers are pale lilac in color, but it never gives a very striking display because the racemes do not display their beauty simultaneously. Commencing to blossom in June, it continues more or less in flower until the end of Summer. A form of this or, possibly, a distinct species, variously

(Continued on page 12)

Teach Horticulture To Foster Love for Plants

P. M. KOSTER

SLOWLY and surely a taste is developing in America for plants and flowers, a love for horticulture. I have seen great changes in the twenty-five years I have been coming to this country. I think that is our duty to further and to foster the love for plants here. We must have something in the future to which to devote our time. More and more the people are working fewer hours. We must try to give them something other than a desire to attend the movies and to speed along the roads at the rate of fifty miles an hour. This can only be done by educating them to love plants. Allow me to point out to you what other countries are doing, in order to give the necessary horticultural instruction and education. Naturally, I am speaking about Holland, the country with which I am most acquainted.

In the first place, there is elementary horticultural training in the Winter courses, for which the state gives a subsidy. Each course extends over two Winter semesters. The teaching is done by the state school teachers, who have acquired the necessary qualifications; qualified practical gardeners are also employed to do the teaching. Students may enter every two years and must not be under fifteen years of age. The course comprises: The elements of natural science, including plant diseases and pests; manures, soils, treatment and improvement of the ground; fruit culture, vegetable and flower culture, arboriculture and horticultural drawing. As far as possible, the instruction is adapted to the requirements of the particular kind of gardening in the location.

Secondary training in horticulture is given in five horticultural Winter colleges. One is in Aalsmeer, flowers; one in Boskoop, nurseries; another at Lisse, bulbs; at Naaldwyk, fruit; at Hoorn, vegetables, and at the Horticultural College at Frederiksoord. The object of these colleges is to give the necessary horticultural education to young gardeners, florists, nurserymen, etc. The schools are divided into two classes and the period of instruction covers two Winter semesters, from October to April. In the Summer months these young men work with their various employers; this way almost everybody can afford to attend these colleges.

Higher horticultural education is given in the High School for Agriculture, Horticulture and Forestry, at Wageningen. This is a three-year course and embraces physics, meteorology, plant physiology, mineralogy and soils, chemistry and agricultural chemistry, botanical terminology, botany, drawing, surveying, arboriculture, fruit growing, vegetable and flower culture, civil law and practical work.

Besides all this valuable knowledge, foreign languages are taught, which is a great assistance to our horticultural education, as it enables us to read horticultural papers in foreign languages. It also prepares the young men for their extensive travels in foreign countries, where they generally go after learning their trade at home.

It is not only in Holland that this horticultural education is given; it is the same in England, Germany, Belgium and France.

That sometimes the knowledge of a foreign language is directly responsible for horticultural gains is illustrated by the way Koster's Blue Spruce was found.

My father, who was the great, great-grandson of a nurseryman, soon understood that in order to make Boskoop a horticultural center, we did need a larger area than Holland to sell our products, and father did all he could to

induce the government to devote time and money to horticulture and to the teaching of foreign languages. He himself had acquired, through self-study, a considerable knowledge of English, French and German. One day, reading in the *Revue Horticole*, father saw a description of the beautiful Blue Spruces of the Rocky Mountains, and read that the botanical garden at Zurich had received seeds of some of the finest specimens. Immediately father wrote for some seeds, received some and one of the seedlings was the Blue Spruce which now is universally known as Koster's Blue. If father had not been able to read French, would the plant have come to life? Would others have seen the great beauty of this plant and would it have been propagated?

This is not the only instance; other plants have been described in foreign papers and propagated. These, otherwise, would have disappeared unnoticed.

In the schools a spirit of competition in growing flowers is created and the schools have many expositions of flowering plants, which imbue the youngsters with a love for plants and flowers. Who is able to grow the best? Imagine the pride of a little girl from poor parents bringing in a beautiful plant and winning first prize!

I think it is our duty to help develop this love for flowers and plants, and show each and all people what can be done with flowers and how they make our life richer, how trees and shrubbery make our homes more attractive.

Conditions have already very much improved since I came to this country first. But we are not doing enough. Let our horticultural associations get busy and our women's clubs. Let them create funds to appoint—let me call them horticultural preachers, who, armed with a great love for plants and with lantern slides, go out and show the people (not the upper 400) what can be accomplished with little expense and labor; show them how the board fences must be replaced by well kept hedges, how a few climbing roses will improve the appearance of their homes, how a few beds of inexpensive bulbs, some perennials, will make their homes attractive, and then—watch how their surroundings will make for a happier life.

We must awaken the vast multitudes to the realization of the needs of plants and shrubs and flowers; we must create in the minds of all a desire to improve themselves, their properties, their communities. This cannot be done by lectures before horticultural clubs and societies; those present there do not need to be awakened. It is the daily paper, the small local paper which must take this task to heart.

One of the saddest features of the lack of horticultural training is the condition the trees are in, lining the streets in the cities. The authorities in charge evidently do not see the need of pruning when the trees are young, and many trees could still be saved if they were treated right. If I compare the almost loving care which is bestowed on trees in European cities, how they are Summer-pruned and Winter-pruned until such time that they can take care of themselves, I feel really sorry for their American brothers and sisters, which, once planted, do not get any care thereafter. Many of you have seen the beautiful Elms lining the streets in Holland, the Linden in Berlin, the Planes in London, the Horse-chestnuts in Paris, all well shaped, symmetrical trees, with stems the same height, forming beautiful avenues, a sight to behold.

Now, what is the remedy for all this? Horticultural

(Continued on page 15)

Insects and Plants

WILLARD N. CLUTE

IT sometimes happens that the gardener, impressed with the visits of butterflies and bees to his flowers, speaks of "beneficial insects," but a more careful consideration of the facts might lead him to conclude that there is no such animal. First, last, and all the time, the insect world is absorbed in its own affairs, ever seeking food, shelter, and a place to breed; always taking what it can and often nearly or quite exterminating the organisms it preys upon. And it has always been thus. Although the flowers of the present produce the nectar and pollen utilized by various insects, and in a sense might be said to provide them with food, it is no voluntary act on the part of vegetation. The insect merely takes what it wants; indeed, it is probable that the activities of the insects are responsible for an increased secretion of nectar in flowers, just as man has, by breeding, increased the secretion of milk in cows.

It is undoubtedly true that our planet began as a flowerless world, and that when the first insects appeared on it they were obliged, like other forms of animal life, to feed on the plants. Representatives of these early races are still with us in the form of bark beetles, wood-borers and the like. The young or larval stages of the great majority still feed on plant tissues, but the mature insect in higher forms has developed a taste for more refined kinds of food. The first flowers were far from being the showy objects we think of when the word flower is mentioned. They appear to have been exclusively pollinated by the wind, and were much like those of the pines, poplars, grasses and hazels of the present, which afford no encouragement to nectar-feeding forms.

Although wind-pollinated flowers do not, as a rule, produce nectar, it is probable that they have always been visited more or less by bees and other insects in search of pollen. As a matter of fact, pollen still interests the insects, for many flowers that are entirely lacking in nectar are still favorite feeding grounds. The nectar, so commonly secreted by flowers, is not exclusively a floral product. The leaves of many flowering plants also excrete it, notably those of the little partridge pea and the cotton plant, and the outer bracts of the peony are widely noted for this feature among black ant circles.

The regular secretion of nectar by the floral parts opened an entirely new chapter in plant evolution. With insect visits reasonably certain the plants were assured that their pollen would be carried directly from flower to flower and were thus able to make several changes looking to greater efficiency. Pollen became sticky so that it would adhere to the visitors, and at the same time stamens and carpels became of different lengths, or ripened at different times, in order to prevent self-pollination. With the production of a perianth to protect the nectar and guide the insects to it, fewer stamens were necessary to accomplish pollination and the plant saved in pollen more than it lost in the production of nectar. Finally the appearance of flowers turned sidewise ensured that the insect would alight in a definite part of the flower and thus could be covered with pollen by still fewer stamens. Thus the stamen number was further reduced until we have whole plant families with but one or two stamens to a blossom and some that manage to carry on business by means of only half a stamen.

The accommodating blossoms have provided in numerous ways for the storage of nectar until the favorite insect calls for it, and have found ways of protecting it from other insects, but even this consideration fails to

impress the greedy visitors which all too often bite through the walls of the nectary and abstract the sweets without pollinating the flower at all. It is small wonder, therefore, that a number of plants with showy flowers have other and less conspicuous ones that never open but make use of their own pollen and produce all or most of the seeds.

Many species of plants have now become so exactly adapted to the visits of a given insect that they fail to set seeds if it is not present. The absence of an insect from a region, therefore, may limit the distribution of various plants in it. More far reaching still, the life of the plant may be so bound up with that of another, through the insect, that the absence of one may limit the other, as in the case of one plant which serves as the host plant to the larval insect that in the mature state pollinates some distant species.

The more usual way in which insects act to limit the spread of a plant species is by exterminating it in feeding upon it. It is quite likely that the potato plant would be exterminated in regions where the potato-beetle is abundant if man did not constantly fight its enemy. A redeeming feature of the picture, however, is the fact that the greedy insects are not content to feed exclusively on plants, but have developed a disposition to eat one another. Even man, himself, does not entirely escape pests of this nature. In numerous instances, however, the safety of the plants lies in this fondness of one insect for another. The ichneumon flies and lady-bugs are ever on the search for plant-eating forms, and the dragon-fly is all that his name denotes with reference to mosquitos. In the larval state the dragon-fly larvæ eat mosquito larvæ, and those that escape and assume the adult form are taken care of by the grown-up dragon-fly. It seems likely that we shall come to depend more and more on the aid of insects that eat others to protect our plants from harm.

Looking at the subject as a whole, it seems just retribution that overtakes the insect world when the plants turn the tables on them and become the eaters instead of the eaten. The sundew with a dozen leaves like small red hands, lies in wait for its prey and, clutching it, turns its leaves into impromptu stomachs and digests its captives. The pitcher-plants provide little wells within their hollow leaves and calmly drown the insects, in some cases cunningly enticing its victims by sugary secretions with which is mixed a substance that stupefies them. There is a long line of these insectivorous plants—butterworts, catch-flies, bladder worts, Venus' fly-traps and the like, but insects are so numerous and multiply so rapidly that they are not much impressed indeed, certain thrifty specimens, eager to capitalize the misfortunes of their fellows, push into the pitcher-plant leaves and lay their eggs in the decaying bodies of its victims.

Doubtless God could have provided us with better fun than hard work, but I don't know what it is. To be born poor is probably the next best thing. The greatest glory that has ever come to me was to be swallowed up in London, not knowing a soul, with no means of subsistence and the fun of working till the stars went out. To have known any one would have spoiled it. I didn't even know the language. I rang for my boots and they thought I said a glass of water; so I drank the water and worked on. There was no food in the cupboard; so I didn't need to waste time in eating.—*Sir James M. Barrie.*

The Orchid

FOR many persons Orchids are associated with thoughts of luxury and opulence, based, no doubt, on the magnificent blooms of the florist shops and the still more gorgeous flowers seen at exhibitions, writes E. I. Farrington in the Christian Science Monitor. Yet many Orchids are modest and shy. The Lady's Slipper of northern woodlands is an Orchid as truly as the giant *Cattleya* of South America. Even the most splendid members of the family hide themselves in the depths of mighty forests, blooming unseen in such vase and colorful shows as have never been staged by men.

Although all Orchids possess practically the same curious physical structure, by which they are set apart from every other plant, yet they are divided into two great classes with totally different modes of living. There are, first, the Terrestrial Orchids, which grow directly in the earth; these are the only kinds found in temperate regions. There are then the Epiphytal Orchids (using a name that falls strangely on unaccustomed ears), which drape themselves over rocks and trees, reveling in heat and moisture, and living often in swamps so dense that hardly a ray of direct sunlight ever penetrates to them. They are not really air plants, although often called so, and neither are they parasites, although they may depend upon some other form of life to hold them erect. Their nourishment comes largely from the mineral matter that collects among their roots.

Orchids inspire no such sentimental feelings as the violet or the rose, but they exercise an elusive fascination above all other flowers. The lure of the Orchid is like the lure of gold. It will tempt men to any length in hardship or exposure. No romances in the annals of horticulture surpass those woven around the world-wide search for Orchids, a search that still goes on, for regions yet remain which the collector has not explored and where untold treasures may await his coming.

For a long time the rare Orchids of the tropics were sought mostly in the interests of private collectors. Then, as more about their culture was learned, commercial growers began to gather them in increasing numbers. So a great industry was gradually built up, thousands of plants being sent every year to the British Isles and to the United States for the trade.

Whole sections in South America have been stripped of their Orchid wealth, but the southern continent is vast and new hunting grounds are constantly being reported. Moreover, the Federal Horticultural Board at Washington has forbidden the importation of Orchids into the United States except by special permit, and then only for propagation. This has stimulated home production, but on the other hand has proved a sad blow to private collectors.

In England, where there are no import restrictions, the seedling raiser is being depended upon far more than ever before, while fewer and fewer new species are coming from the forests. England, however, still imports tons of commercial Orchids, particularly *Odontoglossums* and *Cattleyas* from South America. All that great continent from Mexico south is rich in Orchids, which were known and loved long before the Spaniards came to substitute a harsh civilization for the simple life of the natives. Early historians tell us that choice flowers, and especially Orchids, were daily tributes to the Mexican rulers.

Columbia, Venezuela and Brazil are exceptionally prolific, especially in *Cattleyas*, the type of Orchid most commonly seen in the florist shops of America.

Although *Cattleyas* are the most popular Orchids in

America, the English public prefers *Odontoglossums*, which abound in various parts of the South American continent, fully 100 species having been found in the Andes. If they could be grown as well in the United States as in England, they might find the same high favor, but the Summers are too hot and too dry for producing perfect blooms. On the other hand, the clearer skies give the Americans better *Cattleyas* than can be grown in the British Isles. At their best, it is difficult to choose between them. *Odontoglossums* are often called the loveliest flowers in the world. Yet *Cattleya Dowiana* has been described by an Orchid expert who knows them all, as the "most gorgeous, the stateliest, the most imperial of all flowers on this earth."

While intrepid plant hunters are seeking the hiding places of the *Odontoglossums* and the *Cattleyas* in South American countries, other men, equally venturesome, are roaming India and other Eastern lands. *Cymbidiums* are a particularly important feature of their quest, although these Orchids are now being propagated readily in Europe and America. Until 1900 few *Cymbidiums* were in commerce. Then a species was found which soon appeared in many variations and proved easy to grow, flowering in three or four years. Now these Orchids are among the kinds commonly offered by the florists and are remarkable for their long keeping qualities. They will last for three or four weeks in water and for two or three months on the plants.

For that matter, the flowers of most Orchids will remain fresh for a month or more if not pollinated. Indeed, there is a marked dignity and moderation in all the processes of the Orchid. The capsules wherein the seeds repose may not open for many months to let them free. Nature does her best to perpetuate the plants, however, for there will be from a thousand to a million of these seeds in each capsule.

WISTARIAS AND THEIR TRAINING

(Continued from page 9)

called *W. frutescens magnifica* and *W. Macrostachya*, bears larger racemes and is in every way a better plant.

The propagation of *Wistaria* is relatively easy. They may readily be layered or cuttings of the current season's wood, if removed with a heel as soon as moderately ripe, will root satisfactorily.

As purchased, the plants are almost invariably grafted. Where grafting is carried out on to roots of the same species, it is comparatively innocuous, but plants on their own roots are safer. Grafting is easily carried out in spring under glass with a little bottom heat. It is truly astonishing, however, how grafting persists as a means of propagation for many plants which increase readily, not only from layers, but from cuttings.

In favorable seasons, seeds ripen freely and are easy to germinate. The seedlings do not, however, as a rule, produce very good forms. Seedlings of *W. multijuga*, in particular, are apt to be exceedingly "washy" in coloring and comparatively short of trail. If a good type be secured from seed, it has naturally abounding vigor. Seedlings serve the nurseryman for stocks on which to work better types.—The Garden (British).

He who reveals to me what is in me and helps me to externalize it in fuller terms of self-trust, is my real helper, for he assists me in the birth of those things which he knows are in me and in all men.—IV. John Murray.

The Greenhouse, Month to Month

GEORGE F. STEWART

THE season has arrived when many plants need a general overhauling, especially if one has a tropical house. Late January and early February is as good a time as any to pot or propagate many of these plants. Nice clean tops of *codiceum* (or to take the more popular name *crotons*) should now be selected for propagation. The best method we have found is to root them on the plant. Remove the bark by girdling, where one wishes the top to root. Cut the bark clear round in two circles, about half an inch apart, and use a two-and-three-quarter-inch paper flower pot, which is easy to keep in position by tying to a stake. Get the girdled part well down inside the pot. Use a compost of sphagnum moss, sharp sand, and good loam in about equal parts with some powdered charcoal added. Pot firmly, using great care, as it is very easy to snap the wood at the girdled part. Keep the compost damp all the time until the top roots, which will be in about a month. In a regular tropical house temperature should be 65 deg. at night with a 15 deg. rise during the day. I forgot to mention above that the bark between the two girdled parts should be removed, which is very easily done as it comes off clean. By this method of propagation, one will hardly ever lose a leaf, if, before removing the top from the parent plant, said plant is allowed to become quite dry at the root, keeping the compost damp around the top that is rooting. After the tops are well rooted remove them and pot for a first potting in a four-inch pot in a light compost. Keep them close, in a humid atmosphere, until they begin to root freely in the new compost. We have grown plants four feet high in a six-inch pot with leaves furnished clear down to the pot in one season, that is, from the time of propagation until the following Fall.

If large specimens of *cordylines* (*dracæna*) are required they can be rooted the same as *crotons* by girdling. Nice small table plants, however, may be had in one season by cutting up the woody stems in pieces, about two inches long, covering them with sand in a propagating bed that has 80 deg. bottom heat. The shoots start from an eye in the old wood, and when they have developed a few leaves, may be removed with a heel and rooted as any other cutting, and potted along as they require it. *Dracænas* like a good fibrous loam to grow in, adding about one part leaves to three parts loam with enough sand and charcoal to keep the soil sweet and porous. Add also about a third of dry cow manure to the compost.

Alocasias, to grow them well, must be turned out of their pots each season, and all the old material shaken gently away from the underground stems and roots, and potted. They grow well in a mixture of equal parts of *osmunda* fern root, sphagnum moss, and the fibre of loam with a good sprinkling of charcoal. Mound them up a little in their receptacle. They may be fed a little when growing vigorously.

Anthuriums are divided into two sections, those grown for the quaint shape and beauty of their flowers, and the other section for their foliage. Both sections grow well in compost similar to *alocasias*, only adding more sphagnum moss. *Anthuriums* are also strong rooters, but may be grown in the same pot (if mounded up with sphagnum moss) for two years. *Anthurium Scherzerianum* and its varieties, by judicious treatment, can be grown into hand-

some specimen flowering plants, which by their striking appearance when in flower will always command attention and admiration.

Marantas, now most known under the name *calathea* (the difference between the two being botanical), were once very popular plants, and around Boston twenty to thirty years ago, very fine specimens were to be seen. Where a tropical effect is wanted in some warm corner of the conservatory, these plants, with their fine colored markings, are among the best to be used. They now need attention at the roots and should be examined to see that their drainage is all right. They may be grown in the same pot for several years, in fact, they do not like overpotting. The loose soil may be rubbed off the ball which can be easily done, if they have been kept on the dry side for the last two months. A compost of equal parts of the fibre of loam, half decayed flaky leaves, drier cow manure, with enough sharp sand and broken charcoal to keep the whole in a porous condition is what we have found they delight in. *Marantas* do not like hard potting, just moderately firm. Give them plenty of room to develop their foliage and keep them clear of insects, an easy matter, since the advent of hydrocyanic gas, as a fumigant.

All these tropical plants, noted in the above remarks, like a humid atmosphere and the paths and under the benches, also between the pots, should be kept in a moist condition. Coal ashes we have found are best for covering the benches to set the plants on. There is something about them that is congenial to plant growth, far more so in my experience, that the more clean and artistic looking pebbles, which are commonly used for that purpose.

Adiantum cuneatum and its varieties are very useful in six- and eight-inch pans when grown hard, that is, giving plenty of air when severe Winter weather has gone by and not shading them heavy in Summer. Plants that have been two years in the same receptacle may be divided in two and potted in a good fibrous loam with some ground oyster shells and sand added. If grown in a good house and given plenty of room they will make nice plants next Fall. A large well grown specimen is also a handsome sight and there is generally some corner in the mansion where they look well for a week or two.

There are many other varieties of *Adiantum* that are seldom seen of late years in greenhouses. A few varieties such as *caudatum*, *decorum*, *tenerum*, *trapeziforme*, *gracillimum*, *Williamsii* rise in mind as I write. These all may be grown into fine plants, and are very decorative. The variety *Farleyense*, supposed to be a form of *tenerum*, would need a special article by itself to describe the mode of propagation and culture. *Adiantum*, *Glory of Mordecht* or *Gloriosa*, is in my opinion inferior to the old *Farleyense*. I have never yet seen fronds or plants of it the equal that the late David Allan and David Fisher used to grow, when I worked under them thirty years ago near Boston. Probably some of our young men will say, "Oh yes! There were giants in those days." However, if need be we can produce the witnesses. Many other ferns such as *Davallia*, *Gleichenia*, *Gymnogramma*, *Lomaria*, etc., also the *Selaginellas*, of which there are quite a number of fine forms, need looking over but do not overpot any of them. Large pieces, if they have been well potted, will grow several years in the same pan or tub they may be in.

The drainage, however, should be examined frequently and a little top-dressing given at this season, and after they are growing good, well fed with stimulants, using a little variety.

Large plants of *calceolaria* that are wanted for exhibition in May, may now be given their final shift. The great thing is to keep these plants cool, thirty-eight to forty at night is warm enough unless wanted to flower early. The *stewartii* type we can flower in July, by pinching, potting a few days after they are cut back, and shading. This is the best season to propagate this type, and if large plants are wanted another year, carry over the later struck ones in five- or six-inch pots, or even larger, according to the size desired at flowering time.

Any large fuchsia plants that have been carried over may now be trimmed into shape. Pyramid shape is ideal for fuchsias, and of course, they look very pretty as standards. Keep the growths pinched until eight weeks before they are wanted to flower. Cuttings of these plants that were rooted in August, by February 14 should be fit for their flowering pots. We find nine- and ten-inch pots big enough for the first year. The ball of the old plants may be reduced and potted in the same pot, giving a larger shift later if they start well.

An early batch of *achimenes* can be started now. Space the rhizomes in a tray, the bottom of which has been covered with ground up sphagnum moss. Cover them lightly with a mixture of leaf mold and sand. When the young shoots are about two inches high, space them in the pot or pan they are to be grown in. By starting them into growth first in the flat, growths of an equal strength may be potted in each pan, which will make a more uniform plant when flowering. They grow well in equal parts of loam, leaf mold, and sand, in a night temperature of 60 deg. They must always be lightly shaded from the sun and carefully watered in their earlier stages, never allowing water to lie on the foliage. The more slender varieties make beautiful hanging baskets.

Increase, or renew the stock of *Bouvardia* at this season. They form plants from root cuttings. Bear in mind, however, that slight variations in color are likely to happen with root cuttings. Top cuttings from the young growths root in about a month, if one has a good bottom heat in the propagating bed, and they come true to color.

Batches of cuttings of the general run of bedding plants should now be secured and rooted, such as *coleus*, *heliotrope*, *begonias*, *ageratum*, *lantanas*, etc.

Poinsettias, after they are past flowering, may be laid on their sides near the pipes under a greenhouse bench that is run around 50 deg. night temperature.

Euphorbia Jacquinæflora or *fulgens*, which is also another fine Christmas plant, must be kept on the bench and carefully watered after flowering. A second crop of flowers may be secured if desired, and after that, growing shoots will start on the stems, which when about three inches long, will make ideal cuttings for another season. These two *Euphorbias* are among the best for Christmas decoration, but many do not care for them after that season has passed.

Nerines are now making their growth, feed them well until they show signs of having completed their growing period. Keep them on a good light bench in a cool temperature. I believe these plants will be more largely grown in the near future. Professor Sargent, near Boston, has the finest collection of *nerines* I know of. His veteran gardener, Charles Sanders, is very successful with them and has raised quite a number of new crosses.

Our plant of *Mackaya Bella*, after a slight drying process for the last two months, has now set its flower buds and will be given plenty of water in which soot

has been mixed. After flowering it will be potted and pruned into shape.

Put in leaf cuttings of the beautiful *Saintpaulia ionantha*. Small plants when in flower are most useful subjects for table decoration. They root best in an open propagating bed, as the fleshy leaves are apt to rot in a close case. *Saintpaulias* must be grown under shade and water never allowed to get on the foliage.

Cœlogynes are showing their flowers scapes, and will be benefited by more water. Keep it away from the young growths, as if moisture gets into them they are likely to decay.

Many *cypripediums* are flowering at this season. They enjoy a temperature around 50 to 55 deg. and a moist atmosphere. A very light shading as the sun gets stronger is necessary. Dense shading will result in weak foliage and poor flowers. *Cattleya Percivaliana* is now finishing flowering and *cattleya triana* is commencing. A night temperature of 50 to 55 deg. we find is all right for these orchids, and a very slight shading even in Summer. I never allow them to get too dry, even when seemingly at rest. *Odontoglossum crispum* is now making its growths and should have plenty of moisture in the house at all times. Give them plenty of water, but do not keep them in a soggy condition. Rain water, of course, is best for them. *Calanthes Macwilliamsii*, *Orpetiana* and *Ryanii* are in full flower with us, the earlier ones have gone to rest.

Ventilation is a very important part of the greenhouse man's work at this season. We quite often have zero and much lower temperatures, which necessitates heavy firing, and when the sun comes out the thermometer will mount rapidly. Opening of the ventilators must be done gradually to avoid draughts, and one has to make the rounds of the different compartments quite often for fear of too sudden changes in the temperature. Damping of the floors will help to keep the house cooler, if done frequently during the earlier part of the day. It is better to let the temperature run a little higher with sun heat, when the temperature is low outdoors.

Grapes that have been started early should by the middle of February have had the temperature raised gradually until it has attained 60 deg. all night; allowing it to rise with sun heat; in middle of the day to 80 deg., and then gradually reducing the ventilation as the sun goes down. They should have been sprayed lightly on all bright days two or three times. Borders will need examining frequently to keep them in a uniform moist condition. Watch the young shoots as they break and thin out all the weaker growths, leaving the strongest one to each spur. The rod should be tied in position as soon as an even break is secured all over the vine.

Early peaches and nectarines will also be well advanced and an eye must be kept on the wood that it does not get overcrowded on the trellis. Thin out all the weaker fruits when they are about the size of small hazlenuts. The foliage may be sprayed over until the fruit begins to ripen. Be sure that the pot fruit does not suffer for lack of food and water. The roots being confined into small space, dry out very often, and frequent waterings leach out the plant food.

Keep up a succession of forcing vegetables if room is available. The annual spinach will grow cool along with lettuce. Beans and tomatoes can be kept as high as 60 deg.

Keep thinking ahead as there will be plenty to take up one's attention as Spring approaches.

When any duty is to be done, it is fortunate for you if you feel like doing it; but, if you do not feel like it, that is no reason for not doing it.—*W. Gladden.*

Work for the Month in the Garden

IN nearly all gardens, January is the month of completing odds and ends, for little can be accomplished in the average garden except to put everything in order for the coming season. This, however, is quite important in itself, for it will lighten the work of the busy days ahead. Tools and implements can be cleaned and sharpened; the stock of insecticides, spraying materials, and fertilizers replenished; flower stakes, pea brush, and bean poles made ready for future use; and the manure prepared for the hot beds to be used next month, though care must be taken to protect this material from snow and rain. For good hot beds, there is no better material than fresh horse manure which contains a fair portion of straw litter. If there is not sufficient manure, leaves may be used as a part of the mixture; in fact, the beds can be made wholly of leaves. We do not, though, recommend that more than one-half of leaves be used if manure is at all available. A point of importance in connection with hot beds is to have the material in a fit condition, sweet, and neither too wet nor too dry. There should be no water when the material is held tightly in the hand. After being turned over a few times at intervals of two or three days, the material is then ready for the pit. At first pack quite firm, and after the manure has warmed through again within two or three days' time, tramp it thoroughly. Soil to the depth of six inches should be applied if the seed is to be sown in rows on the beds, but a thin layer of sand or soil should be applied if the seed is to be sown in flats. Hot beds have two distinct purposes; they may either be used to grow a crop into maturity, or merely to give it an early start to be planted outside later.

During the month of January our efforts are mainly expended in the protection rather than the production of vegetables. Careful inspection should be made every so often of the supply stored, and decayed specimens should be at once removed.

If greenhouse space permits, an early start can be made with vegetables, and such crops as carrots, beets, cauliflowers, spinach, and salads sown in a temperature of 40 to 45 degrees. Tomatoes and string beans, which can be raised either in benches or pots, require a somewhat higher temperature, an average of 55 degrees.

Peas and potatoes may also be started in a temperature of about 40 degrees in the bench of a cool house or in pots, with the temperature increasing with their growth. A light porous compost is essential in starting these crops early, as holds true with the majority of young stock during the Winter months. Well rotted cow manure and turfy loam, or loam and leaf mold in equal parts, is excellent for potatoes at this time. Peas thrive well in a compost similar to that required for the successful cultivation of potatoes, to which may be added a little bone meal. If grown in pots, the peas and potatoes may be placed under the bench of a cool house till they are a few inches high. It is, of course, essential that there be good drainage in the bottom of the pots.

With February, work can be commenced in earnest, and as sowings of certain varieties of vegetables and flowers are made, we should think over the successes and failures of the past year, and make plans to avoid the latter in the new season. Some plants may not have thrived because the soil was not suitable, because the

ground was not carefully fertilized, or because seed was sown too early or too thickly. The latter often is the cause for disappointment in growing crops, for many people feel it necessary to empty a whole package of seed when only half is all that is required for the space allotted. The seedlings suffer from over-crowding and it is inviting failure to begin with weak stock. A small number well grown, either of flowers or vegetables, is of finer quality and more productive than a quantity not properly developed because of lack of room.

For outdoor planting, cabbages, cauliflowers, celery, egg plants, onions, peppers, leeks and parsley can be started in the hot beds during early February. Seeds can then also be sown of beans, radishes, lettuce and cucumbers, and annuals for the flower garden may at the same time be sown. For these early crops, the soil should be fairly rich, containing a good proportion of sand and humus. While snow around pits and frames in which are dormant plants is sometimes beneficial, plants in hot beds must have light and air. Frames in which are growing plants, should be ventilated when the weather permits, and decaying foliage carefully picked off.

If there is still pruning of fruit trees to be done, the work, if at all possible, should be completed in February. The pruning of fruit trees is to maintain a proper balance of growth, and to produce fruit of a better quality, and while severe pruning at the time of planting is a wise practice, it is advisable to prune less severely thereafter, especially in the case of stone fruits. A "smother" should be made of all prunings, as it produces an ash which is valuable for fertilizing. It is also the best means of disposing of garden refuse. Spraying of the orchard, ornamental trees, and shrubs for scale insects or fungoid diseases should be done on mild days.

TEACH HORTICULTURE TO FOSTER LOVE FOR PLANTS

(Continued from page 10)

instruction! We must demand that horticulture be taught in schools and high schools, and that a number of horticultural colleges be established. We must ask everybody to help in this movement—the city government, the state, the federal government and, if I am not mistaken, we shall be able to accomplish something in the near future. We are scrapping battleships. We are limiting the building of fortifications. Must we not build something else instead? We must build up the love for the land, the love for the country, the love for our homes—that love which prompts a man to stay on his property, however small and poor it may seem to others—the property where he saw his children born, where he planted his trees when he was young, where he grows his flowers. If we assist in this upbuilding we shall accomplish more, create more patriotism than ever warships or armies will accomplish. It is this love for a country which makes the country safe, makes it unconquerable.

No man is born into the world whose work is not born with him. There is always work, and tools to work withal, for those who will,—*H. W. Beecher.*

Foreign Exchange Department

THE COMMON SPINDLE TREE (*Euonymus europæus*).—If of little or no attraction when in bloom, this low-growing tree in point of color and graceful beauty can hold its own in Autumn with the best introductions from other climes. For this reason it should be planted—freely—in large gardens and on the outskirts of ornamental woodlands. Its beauty was never more apparent than at the present time, for whether on the fringe of the home woods, in the garden, or by the waterside, groups of this graceful tree are alive with color, every tree, whether large or small, being a study of rose pink, the dainty twigs carrying a load of loosely-arranged capsules, which—as they age—will burst and disclose their bright orange-colored seeds, and thus enhance the beauty of the plantations. The branches provide excellent material for indoor decoration, and these are rendered even more attractive by the few remaining leaves, which are suffused with purple.—*Gardening Illustrated*.

RHUS OSBECKI.—A batch of this striking Sumac attracted my attention recently by reason of its large and gorgeous orange red and yellow leaves and curious red-winged leaf stalks. I have on previous occasions admired this as a small tree when in its Autumn dress, and also when covered with its handsome panicles of yellowish flowers, which appear during July and August, each panicle being from 7 inches to 10 inches long. Its great attraction however, lies in its richly-colored leaves, which each measure 15 inches in length and 10 inches wide from tip to tip of the leaflets. In their present state these are decidedly handsome. The plants in question were in lines and about 5 feet in height, and there being several together—in this way—the effect was considerably enhanced when compared with an isolated specimen. This distinct Sumac is a native of China and Japan, and should be grown by all who value rich Autumn color. If cut to the ground each year the leaves resulting from the vigorous young growths are of considerable size, and produce fine effects.—*Gardening Illustrated*.

CRATÆGUS PYRACANTHA.—During the summer the Fire Thorn may pass unnoticed, but when late Autumn arrives its clusters of deep red-orange fruits at once arrest attention. Nor is their display a fleeting one, for the berries last in good condition until well into December in a favorable season. *C. Pyracantha* is perhaps seen at its best when used for furnishing a wall, which its small, dense foliage soon covers. The Fire Thorn can be specially recommended to those who live in towns or in smoky districts, for it does not appear (unlike many other berried plants) to object to town conditions. It is a pity that in towns—generally speaking—berried plants find so few admirers, for they brighten up what would be otherwise rather dingy surroundings after the flowers that give color have succumbed.—*Gardening Illustrated*.

HAWTHORNS.—Many people pin their faith to the double-flowered forms of the common Hawthorn, and they are certainly very beautiful, but they have one great defect, they produce no fruit. Possibly the best of the doubles is Paul's Double Scarlet, a variety with rich, bright red flowers, but *alba plena* and *candida plena* with white, and *rosea plena* with rose-colored flowers are also good.

The Washington Thorn, *C. cordata*, is easily distinguished from all others by its rather small leaves and late flowering period, the white flowers being at their best in July. The fruit is small, scarlet, ripens late, and often remains on the tree throughout Winter. It grows 30 feet high.

C. Azarolus, a native of the Orient, is a very remarkable Thorn, not so much by its white flowers as by its fruits. The fruits are about 1 inch in diameter, apple-like, yellow, orange, red or white; fleshy, sweet and edible. Another Thorn with large edible fruits is *C. tanacetifolia*. This has very hairy leaves and shoots, short stiff branches, white flowers and yellow fruits 1 inch in diameter which bear green, leaf-like bracts on the surface. It is a native of Asia Minor and Syria. In leaf *C. orientalis* is rather like *C. tanacetifolia*, but the leaves and fruits are smaller, the fruits also vary in color from yellow to orange and red.

C. sanguinea, from Russia and Siberia, bears rather small, glossy, bright red fruits, and is a good kind to select. *C. prunifolia* is often regarded as a hybrid between *C. Crus-galli* and *C. macrantha*. It forms a bushy-headed tree 20 feet high, and bears white flowers and deep red fruits freely, but is perhaps most remarkable by reason of the rich autumnal tints of the foliage, which embrace many shades of red, from orange and bronze. — *The Garden*.

THE ORIENTAL BITTERSWEET.—Of all the Autumn fruits few can compare with those of *Celastrus articulatus*, a hardy climber which deserves to be better known. The fruit in the young stage is green and inconspicuous, but is borne freely. When ripe,

the three valves of the fruit open and become reflexed, displaying the brilliant scarlet seeds within. As the inner surface of each valve is golden yellow, the branches are most attractive with their load of gold and scarlet fruit.—*Gardening Illustrated*.

SINGLE ROSES.—Their delicate fragility, their charmingly subtle tints and the ease with which they can be grown are all reasons why they ought to be found in every garden where the Queen of Flowers holds court. The introduction of varieties like Irish Elegance, Irish Fireflame and Irish Afterglow did much to popularize them, and the worth of singles has been further enhanced since the sending out of Princess Mary, Mrs. C. E. Salmon and Isobel. These only need to be seen in bloom, surrounded in most instances with highly colored foliage, to call forth admiration and a desire to have them. Wherever roses are grown today for table decoration one can scarcely conceive an entire absence of singles, which are graceful and charming to a degree.—*The Garden*.

ROSE CAROLINE TESTOUT.—It speaks very much for a variety that, after so long a career, it even now "gets a look in" at exhibitions up and down the country. As an all-round salmon-pink Rose, both for country and suburban gardens, I do not think it has its equal. It has a wonderful constitution, flowers almost continuously from June to late October, and is good in every way. The gardener who loves roses, and, owing to difficulties of situation, etc., often fails with others, finds in this old sort one that does remarkably well and will give him many nice blossoms in the course of the year. It has a most healthy constitution and is almost entirely exempt from mildew.—*Gardening Illustrated*.

ROSE ZEPHYRINE DROUHIN.—This Rose has surpassed itself with me this year, both by its extraordinary vigor and the numbers of its silvery-pink flowers. Bushes here which were struck from cuttings a few years ago have developed as many as a dozen willow-like growths from the base during the present year, reaching a height of 8 feet and of a coppery tint. While this is so the older wood is a mass of deliciously fragrant flowers.—*Gardening Illustrated*.

POLYGONUM VACCINIFOLIUM.—This is a beautiful trailer for a shady and rather moist position, and for draping a large rock is very useful, soon making a veritable curtain of elegant foliage. If trailing over a rock with crevices, the trails will root from the joints, and it can easily be propagated in this way or by laying a stone over one of the rails, when roots will soon form; or it can be rooted easily from cuttings.—*Gardening Illustrated*.

CERASTIUM TOMENTOSUM.—This plant is an excellent one for speedily covering any dry bank, a bank, it may be, formed to hide a rough part of the garden, to screen the rubbish-heap, or perhaps a spot where it is impossible to grow anything except rough plants. The bank, covered with the *Cerastium*, remains neat for many years. All except coarse weeds are smothered, and these may be drawn out readily enough.—*Gardening Illustrated*.

Brief Horticultural Jottings

Our readers are invited to contribute pithy news items of horticultural interest to this column, which, with their cooperation, can be developed into a most interesting department.—Editor.

The Arnold Arboretum of Jamaica Plain, Mass., over which Professor C. S. Sargent is the presiding genius, has just completed fifty years of service. The original endowment fund left by James Arnold consisted of \$104,000 and one hundred twenty-five acres were used originally for the enterprise. There are now more than two hundred fifty acres in the Arboretum, six thousand species and varieties of shrubs, great numbers of which have been introduced by it to the public. The endowment fund now approaches \$1,000,000 and there is a fund for immediate development work of \$125,000. The Arboretum plans in the future to send collectors to still unexplored parts of China and other countries to study diseases and insect pests of trees, to do much hybridizing and quite a variety of other work.

Henry J. Elwes of Colesbourne, Gloucester, England, whose death was recently announced at the age of seventy-six, has been one of the greatest travellers in search of plants, horticulture has ever recorded. While he had not done as much collecting in China as Forest, Wilson, or Kingdom Ward, he had traversed more countries than these noted collectors combined. His journeys included Turkey, Asia Minor, Tibet, India (four times), Chile, Russia and Siberia (three times), Formosa, China, Japan (twice), Nepal, and Sikkim. He was a noted authority on birds as well as trees, shrubs, succulents and bulbous plants of all kinds.

National Association Of Gardeners

Secretary's Office, 286 Fifth Ave., New York

1923 Convention, Pittsburgh, Pa. (Date not decided.)

The aims of the association are to elevate the profession of gardening by improving conditions within it.—To cement a closer bondship among all engaged in, and interested in, gardening—to create a greater confidence between employer and employee.

Co-operating with the Massachusetts Agricultural College, the association conducts a course in training young men for the profession, whereby they obtain theoretical knowledge as well as practical experience.

OFFICERS 1923

President JOHN BARNET, <i>Sewickley, Pa.</i>	Vice-President WILLIAM GRAY, <i>Newport, R. I.</i>
Secretary M. C. EBEL, <i>New York, N. Y.</i>	Treasurer MONTAGUE FREE, <i>Brooklyn, N. Y.</i>

TRUSTEES (For 1923)—Thomas W. Head, D. L. Mackintosh, Arthur Smith, New Jersey; Robert Cameron, Massachusetts; Andrew L. Dorward, Rhode Island.

DIRECTORS—(To serve until 1924) William Hertrick, California; George H. Pring, Missouri; Robert Weeks, Ohio; Thomas Wilson, New York; Harold Bryant, Connecticut; Harry Cartwright, Michigan; H. Ernest Downer, New York. (To serve until 1925) George Wilson, Illinois; James Stuart, New York; William Kleinheinz, Pennsylvania; Edwin Jenkins, Massachusetts; Carl N. Fohn, Colorado; Joseph Tansey, New York; John Tonkin, Pennsylvania. (To serve until 1926) Alexander Michie, New York; George F. Stewart, Massachusetts; Theodore Wirth, Minnesota; George W. Hess, District of Columbia; R. P. Brydon, Ohio; William C. Rust, Massachusetts; Charles Schroll, Wisconsin.

SUSTAINING MEMBERS

New York—Mrs. J. J. Albright, George F. Baker, Edwin S. Bayer, Henri Bendel, Albert Clayburgh, W. R. Coe, Mrs. F. A. Constable, Paul D. Cravath, Mrs. W. Bayard Cutting, Mrs. Charles Daniels, Cleveland H. Dodge, Mrs. David Dows, Frank J. Dupignac, Mrs. Coleman du Pont, Childs Frick, W. H. Grattwick, Daniel Guggenheim, Mrs. W. D. Guthrie, Mrs. B. A. Haggis, Mrs. William P. Hamilton, Mrs. John Henry Hammond, T. A. Havemeyer, Mrs. L. A. Herman, Anton G. Hodenpyl, B. H. Howell, C. O. Islin, Otto H. Kahn, Mrs. Frank B. Keech, W. Eugene Kimball, L. Prentiss, John L. Severance, H. S. Sherman, H. L. Thompson. *Michigan*—J. B. Schlotmann, E. D. Speck. *Indiana*—Theodore F. Thieme. *Illinois*—A. Watson Armour, Harry B. Glow, A. B. Dick, Clayton Mark, Mrs. Julius Rosenwald, Mrs. F. W. Uplam. *Minnesota*—Mrs. Chester A. Congdon, F. H. Stoltze. *Iowa*—Mrs. G. B. Douglas. *Missouri*—August A. Busch, Dr. George T. Moore. *Virginia*—Mrs. Arthur Lee. *Georgia*—Asa G. Candler, Jr., G. Gumby Jordan. *South Carolina*—Robert S. Mebane.

LOCAL BRANCHES

NEWPORT, R. I.: Andrew L. Dorward, chairman; Frederic Carter, secretary.

ST. LOUIS, MO.: George H. Pring, chairman; Hugo M. Schaff, secretary.

NASSAU COUNTY, L. I.: James Duthie, Oyster Bay, chairman; John McCulloch, Oyster Bay, secretary.

BOSTON, MASS.: Robert Cameron, Ipswich, chairman; W. N. Graig, Weymouth, secretary.

WESTERN PENNSYLVANIA: Manus Curran, Sewickley, chairman; Henry Goodband, Sewickley, secretary.

PRESIDENT BARNET'S MESSAGE

Fellow Members:

1922 is now history. We as an association have accomplished a great deal and learned much. If we are to continue to make satisfactory progress, I ask at this time that you all put your shoulders to the wheel and keep up the steady growth so ably maintained in the years past.

Your president alone does not make the association and can accomplish very little without the aid and co-operation of the rank and file. This means you.

With the increase in local branches and a better dis-

semination of information success is assured. As to local branches, I believe they offer a splendid opportunity for the advancement of the association and the profession it represents. Members can get together easily at any time to discuss N. A. G. matters, and get more real knowledge at a small meeting than one would feel disposed to ask at a convention. All that is necessary is to appoint a chairman and secretary, the latter keeping in touch with the national headquarters. It is now squarely up to the localities to do their bit, and I shall be very much disappointed if we do not hear from places like Chicago, Cleveland, and Detroit this year.

In making appointments for 1923, it will be noted that some of the younger men are included which I hope will cause greater interest among the young men in the affairs of the association. The time is close at hand, if not now here, when a new order of things will take place. With all due respect to the men of today, we must look to the rising generation, both employer and employee. Where would we have been had forethought and labor not been expended in our favor.

Interesting young men in the profession we represent, is going apace since the inauguration of the co-operative training by the Massachusetts Agricultural College. Prospects are very bright and other colleges will surely follow.

Some gardeners do realize, but all must, that, due to acts of war, conditions have changed in gardening as they have in every other line of endeavor, and when a man finds that things are not as they used to be, he should not act too hastily. Many men have given up positions only to find that they have had to accept less comfortable and less remunerative ones after being out awhile. Prosperity is usually manifested on country estates, following a business boom, while retrenchment is always the order during unsettled times.

For obvious reasons which might prove profitable, I suggest that gardeners interest themselves in civic matters towards the beautification of communities, home grounds, etc. Also urge increased production of vegetables to help relieve the possible vegetable shortage of crops, due to scarcity of farm labor next season. This, of course, applies more to those localities where there are no horticultural societies which may now be actively engaged in such work. It offers a fine opportunity to any group of gardeners, no matter where located, and may incidentally help influence employers who still think a gardener a gardener only as they know him.

Our committee on Quarantine No. 37 reported progress and is optimistic as to modification in some form. While the horticultural interests in general are divided on the question, there is no doubt in my mind about the gardeners' or their employers' hopes for modification or total abolition. Therefore, let us as an association continue to co-operate with any and all organizations until the desired end is attained.

Our next convention will be held in Pittsburgh before the middle of August, when I hope to welcome a very large delegation. We are most centrally located; it has been said that Pittsburgh is only a night's ride from any place. Don't hesitate to come, even if it takes two or three nights' ride. Many no doubt are wondering what there is to be seen in and around the "Smoky City." We have several interesting things to show here which cannot be seen anywhere else in the country, if not in the world. It will at least be a change. Bring the ladies along, who will be well taken care of.

In conclusion, allow me to say a word about our official organ, the GARDENERS' CHRONICLE OF AMERICA. A paper is in a measure just what its readers make it and I am sure our worthy secretary would only be too willing to

consider any suggestions readers might offer. Since the GARDENERS' CHRONICLE is the organ and not the property of the National Association of Gardeners, I think we ought to be tolerant, and if the time does come, when the association would be prepared to take it over, then, and not till then, could the members demand just what they want, and whether it should be a weekly or monthly. For the present, I consider it a very good paper in the interest of the gardener, and worthy of a place in any employer's library where other periodicals are to be found.

With best wishes for a Prosperous New Year to one and all.

JOHN BARNET.

APPOINTMENTS OF NEW DIRECTORS

President Barnett has made the following appointments to the Board of Directors (to serve until 1926): Alex Michie, New York; George F. Stewart, Massachusetts; Theodore Wirth, Minnesota; George F. Hess, District of Columbia, all of whom are re-appointed; R. P. Brydon, Ohio; William C. Rust, Massachusetts; Charles Schroll, Wisconsin. To succeed William Gray, Rhode Island, Thomas Wilson, New York (1924); to succeed the late Thomas Hatton, Connecticut, Harold Bryant, Connecticut (1924); to succeed William H. Griffiths, Illinois, Harry Cartwright, Michigan (1924); to succeed John Huss, Connecticut, John Tonkin, Pennsylvania (1925).

NEW MEMBERS

Sustaining Members: Asa G. Candler, Jr., Atlanta, Ga. (James Barnett, gardener) and G. Gunby Jordan, Columbus, Ga. (William Atkinson, gardener).

Active Members: Charles A. Mackay, Yonkers, N. Y.; George Tull, Port Washington, L. I.; Frank Ochenden, Grosse Point, Mich.; William Sutherland, Readville, Mass.

AMONG THE GARDENERS

If any of our readers know the present address of Max Reipen, formerly of Toledo; Charles M. Lind, formerly of Stamford, Conn.; or T. V. Kerr, formerly of Valhalla, N. Y., they will confer a favor by making them known to the secretary, M. C. Ebel.

David F. Roy, for many years superintendent of the Moorings, Marion, Mass., the estate of the late Harry E. Converse, has resigned his position and has engaged in the nursery and landscape business at Wakefield, Mass.

Robert Scott, superintendent of the Carnegie estate at Lenox, Mass., has succeeded the late M. J. O'Brien as superintendent of Uplands, the estate of Mrs. W. A. M. Burden, Mt. Kisco, N. Y.

Alex Mackenzie has secured the position of superintendent of the A. V. Davis estate, Oyster Bay, L. I., succeeding John Forbes. Mr. Mackenzie held this position previous to engaging in the florist business, which he recently disposed of.

Mathew J. O'Brien, one of the oldest members of the National Association of Gardeners, and for twenty-two years superintendent of "Uplands," Mt. Kisco, N. Y., was instantly killed on December 14 by the explosion of a boiler he was inspecting in the residence of the estate. Mr. O'Brien is survived by his widow, four daughters and five sons. He was well known in horticultural circles and highly esteemed in his community.

William Reoch, for the past year outside foreman on the J. Pierpont Morgan estate at Glen Cove, L. I., secured the position of gardener on the estate of William B. White, "Hilltop," Princeton, N. J.

MEETING OF THE NASSAU CO., L. I. BRANCH

A meeting of the Nassau Co., L. I. Branch was held on Friday afternoon, December 15, at Parish Hall, Oyster Bay. Owing to inclement weather, the attendance was not as large as it was expected to be, but nevertheless it was a most enthusiastic meeting. Discussions were animated and brought forth some timely suggestions on what the branch should accomplish. Nassau County will have some recommendations to present at the Pittsburgh convention for the welfare of the national association.

James Duthie was elected chairman for the coming year; John McCulloch, secretary; John Forbes, treasurer; Alex Michie, James H. Andrews, and Alfred Reoch were appointed an executive committee with the chairman and secretary ex-officio members of it. To meet current expenses a collection among members resulted in quite a substantial sum being raised, enabling the starting of a treasury fund.

D. L. Mackintosh of New Jersey entertained those present with words of wisdom on what a gardener should and should not be.

M. C. Ebel spoke of the aims of the national association and what it is endeavoring to accomplish. James Duthie and Alex Michie offered suggestions on what the policy of the local branch should be. It was decided to hold at least six meetings of the branch during the year.

BRIEF HORTICULTURAL JOTTINGS

(Continued from page 16)

Primula obconica, while a beautiful decorative plant, poisons many people; poisoning is most probable when the party handling the plant is perspiring. There is no better cure for this and poisons from various other plants, than hot laundry soap, as hot as can be borne; usually one treatment will effect a cure.

All exhibitions of the Massachusetts Horticultural Society will be free in 1923. There will be three very important shows amongst the ten scheduled. On April 5 to 8, will come the Spring show; on September 28 to 30, a great fruit and vegetable show; and on November 2 to 5, the grand Autumn Exhibition.

The Kurume azaleas are becoming quite popular commercially and they propagate easily from seeds and cuttings, and flower when very small. Their uses would seem to be manifold. Planted out in prepared beds in Summer, their rate of growth is really surprising.

Every one does not know that the noted apple, McIntosh Red, which commands a higher price than any other apple in our Eastern markets, is not a native of the United States but of Canada, and that a monument marks the site of the original tree in Ontario.

Years ago we were startled when the Lawson carnation was sold for \$30,000. Now \$50,000 is paid for the stock of a new seedling strawberry of Kellogg's and excites but little comment. Thus have we progressed.

In time to come we shall have arboretums galore in America. We have the Arnold Arboretum now over half a century old; soon we are to have one in Washington, D. C.; the Morton Arboretum near Chicago; and one for the South and another for California are being considered. There is abundant room for all of them.

It does not seem very long since the Godfrey calla was a novelty. Now one florist in the Old Bay State grows more than half an acre of it under glass, and some of his individual dry tubers weighed as much as twenty to twenty-five ounces at planting time.

Clerodendron fallax with flowers of a brilliant scarlet color would seem to be a fine thing for Christmas. Why does not some wide awake grower make a hit with a good batch of it? Plants seed freely and seeds germinate readily and make fine flowering plants the same year.

At a recent Imperial Fruit Show in London, England, eight thousand separate packages of apples were exhibited; for twenty boxes of dessert apples, there were twenty-five entries and about as many appeared for twenty boxes of culinary apples. In 1921, British grown apples were first in both classes; in 1922 they had to be content with second place.

The 1922 Annual List of Novelties of Burnett Brothers, New York, offers a number of novelties and specialties, both in flower and vegetable seeds which will provide some interesting experiments for gardeners to secure something new in their gardens. Write for it.

The outlook for the International Spring Flower Show to be held at the Grand Central Palace, New York, March 12 to 17, is most promising. Some interesting new features are to be introduced. Five entries in the big garden classes have been received, and everything indicates that all past efforts will be surpassed. The Horticultural Society of New York, the Garden Club of America, and the New York Florists' Club, under whose auspices the show is to be conducted, are leaving nothing undone to make the 1923 show a great success.

The members of the National Association of Gardeners in Sewickley and vicinity of Pittsburgh are preparing a program for the annual convention, which will be held in Pittsburgh this year, that will be somewhat different from that of past meetings. They believe that "variety is the spice of life" and intend to furnish variety, especially for the entertainment of visiting members.

LOCAL SOCIETIES

NASSAU CO. HORT. SOCIETY

The regular monthly meeting of the above society was held on December 13. S. Wooland and J. Gailer were elected to active membership. Thomas Twigg, J. Honeyman, and J. Achler were appointed to judge exhibits, and their awards were as follows: Pot of Lorraine type begonias, first, James Kelly; twelve mixed roses, first, John Everitt. E. J. Brown read the annual report which showed that the society was in a strong financial standing. Officers elected are, James Gladstone, president; Thomas Scott, vice-president; E. J. Brown, treasurer; Edward Harris, recording secretary; Arthur Cook, corresponding secretary; William Milstead, trustee. The annual dinner will be held on January 25. Exhibits for January meeting, 12 mixed carnations, pot of Roman hyacinths, plate of mushrooms.

ARTHUR COOK, *Cor. Sec'y.*

SAINT LOUIS ASSOCIATION OF GARDENERS

The St. Louis Association of Gardeners held its December meeting at the Forest Park Greenhouses, December 7, 1922.

M. J. Benda of the Missouri Botanical Garden presented a paper on "How to Arrange and Carry Out a Flower Show." His paper was very interesting and led to considerable discussion pertaining to flower shows in general and our recent St. Louis show in particular.

This was followed by the election of officers which resulted as follows:

John Moritz, president; George H. Pring, first vice-president; Clarence McGovern, second vice-president; S. M. Beer, third vice-president; Prof. H. C. Irish, fourth vice-president; Hugo M. Schaff, secretary; Ernest Strehle, treasurer; L. P. Jensen, corresponding secretary; Wm. Schoenhofer, chairman publicity committee; Anton Lindahl, chairman membership committee; Fred Mueller, chairman information committee; L. Baumann, chairman exhibition committee; Hermann Schwarz, entomologist.

After the meeting the members were conducted through the Municipal Greenhouses, which contain a large variety of fine and well grown plants.

L. P. JENSEN, *Cor. Sec'y.*

WESTCHESTER AND FAIRFIELD HORT. SOCIETY

The annual meeting of this society was held in Greenwich, Conn., December 12, with President Tough being in the chair. Reports were presented by Secretary George Hewitt and Treasurer James Stuart. Officers for 1923 were elected as follows: President, J. Rutherford; vice-president, E. Beckitt; secretary, George Hewitt; treasurer, J. Stuart; corresponding secretary, T. J. Bulpitt; executive committee, C. Aitchinson, W. D. Robinson, J. Kierns, C. Steele. There was a fair attendance and some very good exhibits of flowers and vegetables. First prize for flowers was awarded N. D. Robinson for a vase of Columbia Roses; second prize, W. Smith, Carnations, Princess Dagmar; third prize, J. Tough, Lilium Rubrum. Vegetables: First prize and cultural certificate, W. Sealey, Big Boston lettuce; second prize, J. Linane, cauliflower. A committee was elected to make arrangements for the annual dinner of the society. Discussions followed, James Stuart made some fine suggestions for the advancement of the society and horticulture.

T. J. BULPITT, *Cor. Sec'y.*

The greenhouse portion is 18 feet wide and 33 feet long.

The Most Greenhouse for the Least Money

BY saying *the least money*, we mean the least consistent with undiminished efficiency and assured attractiveness. Just for identification sake, we call it the Number Two House.

In this Number Two Greenhouse with its straight eave, we have simplified all parts of it so that the completed building, including the foundation, will cost you from 20% to 25% less than our curved eave one. If that sounds interesting, you may incline to send for a new booklet just published, called "The Most Greenhouse for the Least Money."

TARRYTOWN (N. Y.) HORT. SOC.

The Tarrytown Horticultural Society held its annual meeting December 28. Considering the demands that are made on most gardeners at this season of the year the exhibition tables were well filled with Begonias, Carnations, fruit and vegetables. Prizes were awarded to exhibitors having the greatest number of points for the year 1922; these were awarded in two sections, one of growers with and the other of growers without glass. The latter winners were as follows: 1, Ed. Kane; 2, Thos. Wilson. Of the growers with glass, Thomas A. Lee won first; Alex. Anderson, second, and Wm. Graham, third.

Our secretary's and treasurer's reports show the Tarrytown Hort. Society is a truly progressive one, both financially, numerically and otherwise. During the past year this society has done a great deal of social and welfare work, both for its members and for the community. It has also taken up the matter of the preservation of our shade trees with the result that frequent meetings are held by an advisory committee representing the society and the trustees of the town. During the past year our trees have been cared for as never before. The society has appointed a tree warden and purchased new equipment for pruning and spraying and the town is rejoicing that our society is able and willing to cooperate in the important subject. Is there anything more pleasing when passing through a town than beautiful trees? Surely this improvement will bring recognition to those that created the inspiration to make them beautiful.

After the business of the meeting was transacted President Wilson gave the chair to F. R. Pierson, who conducted the election and installation of officers, the following officers being elected: President, Thomas Wilson; vice-president, Ed. Kane; secretary, Ed. W. Neubrand; assistant secretary, Harold G. Neubrand; treasurer, John Featherstone; reporting secretary, Wm. Graham; Board of Directors, F. R. Pierson, Charles D. Millard, Isaac Requa, E. W. Neubrand, William Scott, John Featherstone, John A. Grant and William Graham; Executive Committee, William Scott, John Watts, John Thomas, William Graham, William Jamieson; Frank Honeyman; Thomas A. Lee, James McDonald, Alex. Anderson, Abel Weeks, John A. Grant and John Featherstone.

Following the installation a social hour was enjoyed and refreshments were served.

WM. GRAHAM.

Here and There

TREES AND SHRUBS FRUITING IN WINTER

The length of time that fruits and berries remain on the trees and shrubs varies very considerably from several causes. In the first place, it depends how soon the fruits reach maturity, become dead ripe and fall or are eaten by the birds. Some of the Thorns, for instance, we might liken to early and late varieties of apples. A number drop their fruits as early as October, even if not interfered with by birds; others, *Crataegus Carrierei* and *C. cordata*, for instance, usually hang on the trees in attractive beauty well into the New Year. Locality or environment also appears to play a no inconsiderable part in the keeping qualities (so to speak) of the fruits and berries.

The birds, are, obviously, largely respon-

sible for the length of time we are able to enjoy the many ornamental fruits in the garden. In some seasons when there is a shortage of food, possibly the ground frozen, the blackbirds and thrushes soon raid the bushes. Nor do we grudge our feathered friends their daily food. It is delightful to have them with us in the garden, and most interesting to watch them from day to day, always picking out the ripest fruits, commencing usually with the Mountain Ash (*Pyrus Aucuparia*). Fruits which ripen late they leave until last. Timid by nature, the birds seldom venture to feed on the berries growing on trees and shrubs in much-frequented places. This is why the masses of fruits remain so long conspicuously beautiful growing against suburban houses, while away in the shrubbery borders the bushes are already alive with blackbirds and thrushes feasting on the fruits. In some seasons our Holly bushes are almost cleared of berries if we get a sharp spell of frost before Christmas.

Again, the birds are only copying human beings in their partiality for certain fruits. The ground may be covered beneath a tree with plenty of dead-ripe fruits, but another kind on a neighbouring tree is evidently more tasty, judging by the efforts of the birds swinging at the ends of the twigs.

Three *Crataegus* stand out from all the rest as late-fruiting kinds, the fact that they are correspondingly late in flowering giving them an additional value. *Crataegus cordata* (the Washington Thorn) carries its clusters of rather small orange scarlet berries to Christmas, or later if untouched by birds. *C. Carrierei* is one of the handsomest of the family in flower and fruit. At present the bronze, crimson and gold foliage is conspicuous in the autumn sun with large fruits which often hang on the trees until February or March. *C. stipulosa* (*C. mexicana* of the Botanical Register) retains the fruits and much of the foliage until late in the year and sometimes into January. The fruits are yellowish green. It is worthy of note that, though a native of Mexico, it is hardy in this country.

Cotoneasters are represented by two species in particular which are conspicuous at Christmastide and after, and to which birds do not appear partial. *C. rotundifolia* is a semi-evergreen often carrying its foliage and rich scarlet-red fruits until March. It forms a spreading bush 6 feet to 8 feet or more in height. Even better known is *C. frigida*, remarkable alike for its wealth of red berries and the length of time they retain their beauty. Usually seen as a large wide-spreading bush, this Cotoneaster can be trained into a tree with a good thick-set trunk. The fruits often provide a remarkable contrast to the new soft green foliage in spring.

Several Barberries deserve attention as fruiting bushes in midwinter. Two of the most constant in the production of berries are Barberries *subcaulialata* and *B. Stapfiana*. Both are Chinese species, forming wide-spreading bushes, some 3 feet or more in height with gracefully arching branches laden with carmine-red fruits. The berries of *B. subcaulialata* are brighter in color and have less "bloom" on them than those of *B. Stapfiana*.

A shrub or small tree which the birds appear to leave severely alone is the Sea Buckthorn (*Hippophaë rhamnoides*). It has clusters of orange berries lasting in beauty from autumn until February or March. Non-success with this valuable seaside or waterside plant is usually traceable to the fact that only one sex is grown. Male and female flowers are borne on separate trees, and both must be grown fairly close together to obtain fruits.

We Are Telling It To You As She Told It To Us

"You recall that advertisement of yours, about having one of your crystal gardens so located that one could look right out the window and see the flowers a bloom in its perpetual summerland, regardless of whether it was December or May?"

Straightway after reading it, I sent for your catalog, and looking through it slowly, leaf by leaf, lingered at the one on Page 27. Turning to the window, I looked out and saw it in my mind's eye, just as it would look.

After which you know what happened.

Looking up from my writing this, the yard is piled with snow drifts and the wind is howling like a hungry wolf, but it is perpetual summer in the bloom filled greenhouses. They are filled with flowers and I am filled with the joy of their possession."

That's what this contentment filled owner of two of our houses recently wrote to us.

Her first move to their possession was to send for a catalog.

Seedsmen and Florists

35 and 37 Cortlandt Street,
NEW YORK CITY

Pernettya mucronata is a spreading evergreen shrub two to four feet high, giving a wealth of brilliant fruits the size of peas and varying in color from waxy white to blackish purple and including rose, lilac and mauve. *Pernettyas* are readily raised from seeds, but as only a portion of the seedlings produce really shown fruits, to reproduce these true increase should be by layering or by cuttings. To improve the type, however, recourse must be obviously be had to raising and selecting seedlings. The *Pernettyas* usually retain the fruits until the early months of the new year.

The Snowberry (*Symphoricarpus racemosus*) is too often a neglected shrub. Grown in deeply trenched and well manured ground, it produces quantities of large white fruits weighing down the branches. The Siberian Crab (*Pyrus baccata*), the cultivated garden form, not the wild type, is the last of the Crabs to drop the cherry-like red fruits, often after Christmas.

Last, but far from least, though it is a British wild climber of the hedgerows, mention must be made of the Traveller's Joy or Old Man's Beard (*Clematis Vitalba*), decking all and sundry over which it can ramble with its abundant silky fruits.—*The Garden*.

PRESERVATION OF NATIVE NEW ENGLAND PLANTS

A Society for the Preservation of Native New England Plants has been formed under the auspices of the Garden Club of America and the Massachusetts Horticultural Society.

Its object is to encourage and educate the people of New England to protect native plants and wild flowers from destruction, to cut them only with care and discrimination, leaving the rarer specimens to multiply themselves, and to spread a knowledge of their habits and cultural requirements among the community at large.

This Society plans to provide free lectures, hold exhibitions, plant wild flower sanctuaries, and to spread knowledge and love of wild plants, believing that once the people have learned about them they will become their guardians and stop their rapid extermination.

At present the native Laurel is in great danger, being used in immense quantities in decorations at all seasons of the year, especially at Christmas time. For example, one yard of "Laurel rope" contains twenty years' growth of a large plant. In New

Indian Summer

A Snapdragon of truly
Regal Size and Color

Indian Summer is so unusual in size and so entrancing in color that any adequate description must seem like hyperbole.

Imagine a snapdragon, its flower spikes borne on a stem equaling the gladiolus in height and vigor with individual blooms at least a third larger than the largest of the so-called giant snapdragons hitherto produced, and as for color—a rich, velvety copper red—but, no, imagination fails here as well as description! A few plants in your own garden will make you a far more enthusiastic admirer than reams of adjectives.

Better order at once—the supply is limited, the demand increasing daily.

53 BARCLAY STREET, NEW YORK, N. Y.

Toronto, Canada

London, England

England, motorists have already destroyed great quantities of this, one of the most beautiful shrubs in America.

Many wild flowers, which twenty years ago were common, are now seldom found, and unless the people are willing to protect rare and easily exterminated species, they will soon be lost to New England. For example, the Magnolia or Sweet Bay has from overpicking practically disappeared from the swamp in the town of Essex County, Massachusetts, to which it gave its name and which was the only place in New England where this fragrant flower grew naturally.

The annual membership is placed at \$1.00 with Junior members (under eighteen years) no dues, except to pay ten cents for a button of the society. Sustaining members pay \$5.00 or more.

Further information may be had from Mrs. S. V. R. Crosby, care Massachusetts Horticultural Society, 300 Massachusetts Avenue, Boston, 17, Massachusetts.—*Hort. Society of N. Y. Bulletin.*

WILD FLOWER SANCTUARIES

The action of Vermont in putting certain groups of wild flowers and ferns under protection similar to that given to wild animals by game laws has the approval of all who are interested in the preservation of American plant life. By the Green Mountain State enactment it is made unlawful for any person in any one year to take more than a single uprooted specimen, or more than two cuttings, of any of thirty or forty named plants, and specimens may be taken for scientific purposes only. The penalty for violation of the law is a fine of \$10. The restriction does not apply to owners of land on which the plants grow.

Just as there are bird sanctuaries in certain States and in Canada, Vermont thus becomes a wild plant sanctuary. It is a distinction other States might with advantage secure for themselves. The devastation of wild plant life in New York, New Jersey, Pennsylvania and practically all of New England which has been going on in recent years means extermination of many beautiful wild flowers.

The trailing arbutus presents a case in point. Ten years ago this daintiest and most fragrant of early Spring flowers could be found in abundance within a comparatively short distance of New York city. It is now fast becoming a rarity. The automobile and the thoughtless automobilist are pursuing it even into the remote recesses where it has hitherto blossomed in safety.

What with forest fires and quarrying operations, the unescapable forces of destruction are numerous enough to wipe out the last vestiges of many beautiful wild plants.—*N. Y. Herald.*

During the past year it has been the privilege of the Davey Tree Surgeons to co-operate with a larger number of estate superintendents in the saving of fine trees than ever before, in the history of the organization.

Among the hundreds of gardeners and superintendents who have expressed their approval of Davey Tree Surgery during 1922 are those whose pictures appear on this page—representing some of the largest and most beautiful estates in the country.

Every gardener and estate superintendent has a most important work in the saving of trees under his care. Davey Tree Surgery brings to his aid the highest development of science plus a generation of experience. A careful examination of your trees will be made by appointment.

BURPEE'S SWEET PEAS

Burpee's
Honor
Bright

BURPEE'S SWEET PEAS are world famous. They are grown on Burpee's Floradale Farms in California where soil and weather conditions combine to produce plump, well-ripened, and full-of-vitality seeds. The varieties listed below are all of the Summer Flowering type and they should be sown as early in the spring as the ground can be worked into a fine and loose condition.

BROCADE. This fine art shade is a combination of salmon, rosy lavender and rose-pink with a satiny finish. **Pkt. 10 cts.; oz. 50 cts.; ¼ lb. \$1.50; lb. \$5.00.**

BURPEE'S GIANT WHITE. This is truly the finest black-seeded white Sweet Pea in existence. The flowers are of enormous size, well-waved, and borne in fours on long and strong stems. **Pkt. 15 cts.; ½ oz. 80 cts.; oz. \$1.50; ¼ lb. \$4.50; lb. \$15.00.**

BURPEE'S HONOR BRIGHT. This beautiful Burpee novelty for 1923 is a deep rose-pink on cream ground. The flowers are enormous in size and of exceptionally fine form. **Pkt. (20 seeds) 25 cts.; 5 pkts. for \$1.00.**

BURPEE'S LILAC-PINK. This grand Burpee novelty for 1923 is a beautiful lilac-pink with large, well-waved flowers borne on long stems. **Pkt. (12 seeds) 25 cts.; 5 pkts. for \$1.00.**

CHARITY. The blooms are a brilliant crimson which does not burn in the brightest sun. Well-waved, carrying four flowers on a stem. **Pkt. 10 cts.; oz. 35 cts.; ¼ lb. \$1.00; lb. \$3.50.**

CHERUB. One of the most attractive of all picotee varieties with rich cream ground edged with bright rose. **Pkt. 10 cts.; oz. 35 cts.; ¼ lb. \$1.00; lb. \$3.50.**

COMMANDER GODSALL. The color is an attractive shade of rich violet blue. Large, well-waved, and fluted flowers. **Pkt. 15 cts.; oz. 60 cts.; ¼ lb. \$1.80; lb. \$6.00.**

DAINTY. The flowers are large, well-frilled, and have a beautiful and distinct pink edge around a white ground. **Pkt. 10 cts.; oz. 35 cts.; ¼ lb. \$1.00; lb. \$3.50.**

DAISYBUD. The color of the flowers is a harmonious combination of apple-blossom tints with a suffusion of scream-pink. **Pkt. 10 cts.; oz. 45 cts.; ¼ lb. \$1.35; lb. \$4.50.**

ELEGANCE. The color is blush-lilac or white faintly suffused with a pinkish lilac, giving a most artistic and altogether charming effect. Robust and free in habit and of enormous size. **Pkt. 10 cts.; oz. 45 cts.; ¼ lb. \$1.35; lb. \$4.50.**

FIERY CROSS. The standard is a scorching deep cherry-red with an orange suffusion. The wings are rich cherry-orange. **Pkt. 10 cts.; oz. 35 cts.; ¼ lb. \$1.00; lb. \$3.50.**

FLORADALE FAIRY. This is a very attractive rich deep cream flower of large size and exquisite form. Blooms freely in four-flowered sprays. **Pkt. 10 cts.; oz. 35 cts.; ¼ lb. \$1.00; lb. \$3.50.**

FLORADALE PURPLE. This Burpee introduction is, without question, the finest Sweet Pea ever introduced. The flowers are large, well-waved, and of good form. **Pkt. 15 cts.; ½ oz. 80 cts.; oz. \$1.50; ¼ lb. \$4.50; lb. \$15.00.**

FORDHOOK ORANGE. This magnificent Burpee novelty is truly the brightest orange in existence. **Pkt. (12 seeds) 25 cts.; 5 pkts. for \$1.00.**

HAWLMARK CERISE. An outstanding variety with large flowers of a glowing rose-cerise on cream ground. **Pkt. (20 seeds) 25 cts.; ½ oz. \$1.05; oz. \$2.00; ¼ lb. \$6.00; lb. \$20.00.**

HAWLMARK LAVENDER. This is a beautiful true lavender of exquisite form and largest size. **Pkt. 15 cts.; ½ oz. 40 cts.; oz. 75 cts.; ¼ lb. \$2.25; lb. \$7.50.**

HAWLMARK PINK. A remarkable addition to this class. Of a rich rose-pink shade flushed with salmon. **Pkt. 10 cts.; oz. 40 cts.; ¼ lb. \$1.20; lb. \$4.00.**

HAWLMARK SALMON-PINK. Rich deep pink attractively tinted with salmon and orange. Very large and free-flowering. **Pkt. (20 seeds) 15 cts.; ½ oz. 80 cts.; oz. \$1.50; ¼ lb. \$4.50; lb. \$15.00.**

IMPROVED MARGARET ATLEE. An outstanding clear pink variety which has quickly become a great favorite on account of its size, good form, and magnificent coloring. **Pkt. 10 cts.; ½ oz. 40 cts.; oz. 75 cts.; ¼ lb. \$2.25; lb. \$7.50.**

KING WHITE. Remarkable for the glistening purity of the whiteness and the perfect finish of the flower. Of truly gigantic proportions. **Pkt. 10 cts.; oz. 35 cts.; ¼ lb. \$1.00; lb. \$3.50.**

LIBERTY. A brilliant glowing salmon with an orange cast and perfectly distinct from all other salmon varieties. **Pkt. 10 cts.; oz. 50 cts.; ¼ lb. \$1.50; lb. \$5.00.**

MRS. CUTHBERTSON. The standard is rose-pink and the wings are white flushed with light rose. **Pkt. 10 cts.; oz. 35 cts.; ¼ lb. \$1.00; lb. \$3.50.**

NEW WEDGWOOD. There is nothing finer in the blue section than Burpee's New Wedgwood. The color is a lovely shade of bright blue. **Pkt. 10 cts.; ½ oz. 40 cts.; oz. 75 cts.; ¼ lb. \$2.25; lb. \$7.50.**

ORCHID. A rich shade of lavender with a pink suffusion. The plants make a strong sturdy growth and bloom very profusely. **Pkt. 10 cts.; oz. 40 cts.; ¼ lb. \$1.20; lb. \$4.00.**

PINK PEARL. A pleasing novelty of a clear pearly pink shade. The flowers are large, well-waved, and borne freely in fours on long stems. **Pkt. (40 seeds) 15 cts.; ½ oz. 35 cts.; oz. 60 cts.; ¼ lb. \$1.80; lb. \$6.00.**

RAVENSWING. A striking novelty of an intense shade of blackish maroon. It is the darkest of all Sweet Peas. **Pkt. (20 seeds) 25 cts.**

ROSALIND. Burpee's Rosalind is a revelation of daintiness and beauty. The flowers are a rich rosy carmine; in size and form it is one of the very finest. **Pkt. 10 cts.; ½ oz. 40 cts.; oz. 70 cts.; ¼ lb. \$2.10; lb. \$7.00.**

SCARLET DUPLEX. Truly glorious duplex flowers of giant size and a pure bright scarlet color. **Pkt. (20 seeds) 15 cts.**

SPARKLER. A great flower, combining a bright rose standard with wings of a lovely shade of rosy cream. **Pkt. 10 cts.; oz. 35 cts.; ¼ lb. \$1.00; lb. \$3.50.**

TANGERINE. Deep orange, almost approaching the color of a tangerine-orange. The flowers are large and well-waved. **Pkt. 10 cts.; oz. 50 cts.; ¼ lb. \$1.50; lb. \$5.00.**

THE PRESIDENT. Dazzling orange-scarlet flowers of immense size and good form. **Pkt. 10 cts.; oz. 35 cts.; ¼ lb. \$1.00; lb. \$3.50.**

Vermilion Brilliant. An intense pure scarlet of splendid form and heavy substance. Blooms very freely. **Pkt. 10 cts.; oz. 35 cts.; ¼ lb. \$1.00; lb. \$3.50.**

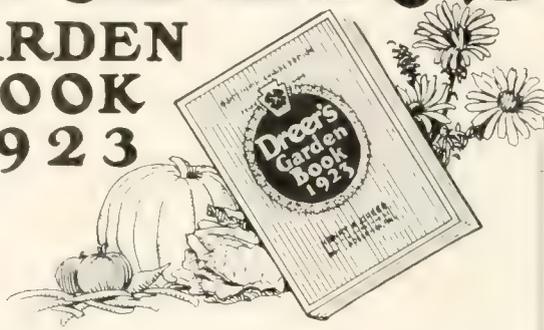

BURPEE'S ANNUAL is the LEADING AMERICAN SEED CATALOG. It fully describes the Burpee Quality Seeds and gives a complete list of Early Flowering Sweet Peas on pages 108 to 110 and Summer Flowering Sweet Peas on pages 111 to 118. Write for a free copy of Burpee's Annual.

GARDEN BOOK 1923

The most complete catalogue of Seeds and Plants published. A large book of 224 pages with 8 color plates and hundreds of photo-engravings of Flowers and Vegetables. Invaluable to amateur and professional gardeners for the cultural information compiled by experts and from Dreer's 85 years' experience.

It offers the best Vegetable and Flower Seeds, Lawn Grass and Agricultural Seeds, Garden Tools and Implements, Fertilizers, Insecticides, etc. Also Plants of all kinds, including the newest and best Roses, Dahlias, Hardy Perennials, Garden and Greenhouse Plants, Bulbs, Hardy Climbers, Hardy Shrubs, Water-Lilies and Aquatics, Small Fruits, etc.

Write to day for a copy, and plan this year's garden now. Mailed free if you mention this publication

If you're planning on a new greenhouse, you'll be interested in what others say about

King GREENHOUSES

Here are a few excerpts from letters in our files:

"The greenhouse you built for me is a very fine and beautiful glass house."

"I wish to say that the greenhouses you installed on my place for rose work and experiments have turned out most satisfactory in every way."

"We had great quantities of ice on the roof owing to the snow and rain freezing and your construction stood the strain splendidly with no bad results of any kind."

"I am both pleased and proud of the whole job and let me at this time thank you in vindicating me (by your good work) in my selecting you to build the greenhouses."

King greenhouses for private estates not only have strength but harmonize with and add to the beauty of their surroundings. They are reasonably priced, economical in upkeep and operation and are giving satisfactory service on hundreds of estates in every part of the United States. Write for catalog 52A which we shall be pleased to send without cost or obligation.

Sutton's Seeds

THE best gardeners choose Sutton's Seeds year after year, because they know the name Sutton stands for leadership in plant breeding. For more than a century the name, Sutton's Seeds, has meant the purest strains, hardiest plants and surest germination of seeds. All over the world Sutton's Seeds are spreading the choice beauty of English gardens in vastly improved strains of flowers and vegetables.

The seventy-seventh annual issue of our Garden

Catalog and Amateur's Guide is valuable not only for the descriptions and classifications of the numerous varieties of all flower and vegetable seeds, but more so for the splendid informative cultural notes which are the result of many years of intensive study and hard work.

Send 35 cents for this helpful book. We credit this amount to your first seed order amounting to \$8.00 or more. You should send immediately for your copy of the catalog. Address Department D.

CALIFORNIA HYBRIDIZED DAHLIA SEED

This seed is raised from California's finest and largest prize winning varieties, which are the finest in the world. This mixture contains all types and colors. Our long, rainless California summers around San Francisco Bay makes it possible to produce hybridized seed of the very highest quality.

The seed we have sent out in previous years have produced many superior varieties. The seedlings will commence to flower two months after sowing, almost a month earlier than plants raised from bulbs.

Price per 100 seeds, Private stock \$3.00
Price per 50 seeds, Private stock \$1.50

POMPON DAHLIA SEED

This class produces small double flowers in great profusion. Splendid for cutting owing to their keeping qualities.

Price per 100 seeds \$1.50

E. A. ASMUS Belvedere, Marin Co., Cal.

A LETTER FROM A NOTED DAHLIA SPECIALIST

Albion, Penn., November 25, 1922.

My dear Mr. Baldwin:

As you know, I have been trying to find time to tell you about my seedling "Dahlia," but you pressed it out of me last spring. I have a very large white flower, a medium to large yellow variety, Sherwood, another also very large, in double or semi-double form, and all the best in form and coloring.

Some years ago, I had a very fair to reduce others; for, one bright seedling, one of a double, and another double, rose colored, cream colored, and one of a double, semi-double, and propagating for stock. Some of the best seedlings I have ever seen, although not quite so large. I have seen many other seedlings that I have seen, but none of them are the greatest I have ever seen. California growers have been an enthusiastic advocate of the California Hybridized Seed, and many others are growing. The coupled seedling, which is the best, and the best of all, growing season which produces the best results, and the best results of vitality and bloom production, and the best results, from your seeds, when grown in California.

I am sure you will find that the best of seedling plant from California.

Most cordially yours,

(Signed) CHARLTON B. BOLLES

ORCHIDS

If you contemplate buying Orchids, send for our special list. Large stock of Laelia Cattleyas, Brasso Cattleyas, and other choice Hybrids.

We specialize in supplying the private trade. Let us figure on your requirements.

Orchid peat, live sphagnum moss, baskets, pot hangers, always on hand.

Save Your Time And Serve Your Lawn

In the many busy minutes of a gardener's day, the lawn may invite neglect—not that he loves it the less, but mowing great areas by hand is a long, slow task.

Coldwell ingenuity has once again made a contribution to the cause of good lawns, and in the powered Model "L" featured here, large expanses of green turf may be mowed and rolled, at one operation, to the extent of six acres a day if needed.

Flexible as the hand mower, and as light running; wide of cut, and easy to operate, the Model "L" is a time and energy saver costly to be without.

Then, too, Coldwell helps you to build better lawns. "Keeping The Lawn" is a little booklet of short cuts and lawn kinks. Ask your dealer for your copy—or, write direct.

Things and Thoughts of the Garden

WILLIAM N. CRAIG

WE have been accustomed for a number of years to consider China as the plant collector's paradise, and that it is such no one will question, as the many fine things introduced from there in recent years by Reginald Farer, William Purdon, F. Kingdon Ward, and Ernest H. Wilson will testify. After listening, however, to an address in Boston by Adolph Müller of Norristown, Pa., on a recent trip to the great glacier section of Alaska, it is very evident that we have within our own possessions many wonderful floral treasures, growing there in great numbers which equal anything that China has given to us. The absence of Ericas in a state of nature in the United States has often been remarked, but in Alaska, Mr. Müller tells us, there are numerous varieties growing in profusion. There are also Callunas (Scotch heathers), silenes, Epilobiums, gentianas, saxifragas, lupines, genistas, pines, spruces, willows, and many other plants, most of them entirely unknown in this country.

* * *

Mr. Müller brought an interesting and lovely little specimen of *Lonicera nitida* with him; this should make a fine rock plant. He also gathered some two thousand specimens which he will distribute to various societies for their herbariums. He considers this little known northland a country of such promise for plant collectors that he hopes the government will organize an expedition to explore its as yet almost unknown horticultural treasures. Incidentally Mr. Müller states that in Alaska one has a most voracious appetite, that in August frosts occurred nightly, and that on August 26 and 27 his tent was buried in three feet of snow, from which it will be assumed that ordinary Summer camping outfits will hardly suffice there.

* * *

Now that rock gardens are becoming increasingly popular, surely we should be able to obtain many useful plants, in addition to herbs, from Alaska which might succeed in such gardens, where in addition to willows, pines, and spruces, there are currants, gooseberries, huckleberries, and other interesting plants. Now that the powers that be make it more and more difficult to bring new plants in from abroad, surely an earnest effort should be made to get what we can in the way of new and useful plant material from our own possessions.

* * *

Not many years ago, women in horticulture were looked upon as jokes, and there are still not a few men who put

them into that category. Women gardeners and florists were increasing in number before the war, and we all know that during that colossal struggle, they performed yeoman service horticulturally. But for their service many private estates as well as commercial plants could not have kept going. The passing of the war has somewhat changed conditions, and both here and abroad, the number of women actively engaged in horticulture has undoubtedly decreased. However, it is cheering to know that a good many quite successful garden advisers, landscape gardeners, florists, fruit growers, gardeners, and retail floral store operators are women. This is as it should be; there certainly could be no more interesting or finer calling for them. Women, we know, have their physical limitations, but when it comes to color arrangements in the garden, creating a simple and pleasing restful effect, or using flowers to the best advantage indoors, they can usually give points to mere man.

* * *

Both in Pennsylvania and Massachusetts we are fortunate in having schools of landscape architecture for women, and each of these institutions has turned out students who are doing at least as well as men. It may be charged that women's ideas are impractical, but in my experience, they are no more so than men's. The average landscape architect should be fundamentally an artist, his or her profession is really architectural rather than horticultural, and it is on this account that so many of them fail dismally, when they essay to use plant material of which they have a rather imperfect knowledge. Many of them plan architecturally very well, but they would in many cases have been well advised had they acquired the services of a first class professional gardener or nurseryman to overlook their planting. If this were done, estate owners would not be constantly pulling to pieces and changing the work of landscape architects.

* * *

But to refer once more to women landscape architects and their training schools. At Lowthorpe, Groton, Massachusetts, is one of these schools, charmingly located some thirty-six miles from Boston. Here are to be found well planted rock gardens, a rose garden, iris garden, a sunken garden, annual garden, and perennial nursery; here also are fruit trees in quantity, vegetables, and greenhouse plants. This school has a most efficient corps of instructors and has turned out some very good material. It is this season trying the experiment of a special course for amateurs, covering all types of gardening, roses, iris, peonies,

soil preparation, mulching, propagation, seed sowing, etc. The course will run from April 3 to May 17, and should appeal to many amateurs. The Lowthorpe School deserves commendation for this earnest effort to interest the increasing army of amateurs, and I trust that it will meet with every success.

* * *

It is not usually the large, expensively constructed flower gardens which appeal to us the most. Too often these are correctly stigmatized by the famous art critic, John Ruskin, as "ugly things." How many of these gardens are really interesting and satisfying? Those which have given me the deepest pleasure, and would have satisfied Shakespeare himself, had no landscape architect to design them, but are the work of the owner assisted and encouraged by his or her gardener. In some cases, no gardener was even employed, but the results were simply delightful. In the last ten years I have visited a considerable number of notable private estates, but the fingers on one hand would more than count all that were appealing and pleasurable, and which made me feel that I would love to linger there.

* * *

Of course, our tastes are quite dissimilar, else we would not have so many varied types of gardening, all of which undoubtedly give pleasure to some. Blue gardens, pink gardens, yellow gardens, annual gardens, bulb gardens, hardy perennial gardens, Italian gardens (Americanized), French gardens, English gardens, all have their adherents. Most of them are formal, usually because they fit with a certain scheme which necessitates their being so. The informal or natural garden does not appeal to everyone, but after gazing at a wide assortment of formal plantings whose dead flowers are removed, plants neatly staked, bad colors religiously culled, and weeds allowed no foothold, what an infinite relief it is to see something informal, where there are no large masses of color, where one sweeping glance can not take in the whole garden, and where new objects of interest and beauty present themselves at every turn! Yet everyone does not see things in this light, and what we revolt at will please others; perhaps it is best that this is so. Our ideas are probably circumscribed, and as we advance in years, we may be over critical and more difficult to please. We cannot agree with Louise Shelton, who in the preface to her book, remarks that the person who has read the book has little more to learn. When we reach that stage, it is time we quit this mortal sphere.

* * *

The debarring of new, rare, and desirable plant material from abroad makes it necessary for us to utilize more of the material we have on hand. The *Malus*, or ornamental crab apple family, is one not sufficiently planted and appreciated. Due to the use of improper stocks, some varieties of these beautiful flowering trees are not lasting as they should. The beautiful Bechtel's double flowering crab apple is a notable example of how a handsome tree can be killed in a few years by using a too vigorous or too feeble stock. The lovely *malus*, *Arnoldiana*, is another example. Of the better known crab apples, *M. floribunda* is probably the most universally popular; like many of the varieties it is also very attractive when in fruit. A few other very beautiful ornamental *Maluses* are *Parkmanii*, synonymous with *Halleana*, and a form of *floribunda* with large semi-double rose colored flowers. It is commonly called the Parkman crab, in honor of Francis Parkman of Boston. Another *floribunda* form is *atro-sanguinea* with very dark flowers. The Chinese *spectabilis* with lovely semi-double, pink flowers makes a handsome tree as does *Scheideckeri*. There are quite a

number of excellent ornamental crab apples, and it is pleasing to know that wide-awake nurserymen are taking these up more. They are not adapted for a mixed shrubbery, but make beautiful lawn specimens and should always be planted where they can show their full individuality. For anyone desirous of planting but one or two sorts, I would recommend *M. loensis* Bechteli, the double form of our prairie crab apple; its large double, pink flowers are as sweet as any tea rose, and it is the latest of the forms to flower. *M. floribunda*, a wide spreading, rather low growing variety; *M. Scheideckeri* of pyramidal habit with large semi-double flowers; *M. Arnoldiana*, a form of *Scheideckeri* originated at the Arnold Arboretum, of bushy habit and carrying much larger flowers, and *M. Parkmanii*.

* * *

I have read with interest the report of the trials of new dahlias at Storrs, Conn., for the last season. Forty-eight growers sent in one hundred thirty-six new varieties against one hundred twenty-four in 1921, one hundred-sixty in 1920, and forty-five in 1919. This makes a total of four hundred sixty-five dahlias in four years and does not by any means cover the entire country. Dahlias are very popular flowers with a large and constantly increasing number of growers, but the sending out of such a host of novelties is utterly bewildering and senseless. What amateurs want is a "boiled down" list of good varieties, say ten peony-flowered, ten decorative, ten cactus, five singles, five shows, five pompons, and so on. Those issuing catalogues, who will send out such a list deserve support and commendation. There is today too much aping after size, the mammoth flowers of today are not decorative and cannot hold a candle with singles and cactus when it comes to real artistic arrangement. We want very much a race of dahlias of moderate height which will throw flowers well above the foliage and prove free blooming. Why not offer inducements to those who can give us fragrant dahlias? The American Rose Society allows but five points out of one hundred for fragrance, the American Carnation Society the same. Is it not time we took forethought and encouraged more the addition of fragrance? Even the American Peony Society allows ten points for fragrance, and the time is not far distant when we shall have scented gladioli.

* * *

Free seeds have been killed, at least temporarily. The cutting off of this Congressional graft has greatly agitated some of our national legislators and they will no doubt make earnest efforts to try to bring back the old order of things another year. We are threatened with the exclusion of all bulbs at no distant date, probably we can produce some varieties here, others we cannot. In this connection it is interesting to note that the Department of Agriculture has for some years had a bulb farm in Bollingham, Washington, and has been experimenting with tulip production on a moderately large scale. They have recently issued a most interesting and valuable pamphlet on tulip bulb production in America, and it would well repay all bulb growers to secure and study this bulletin. The author, David Griffiths, has done some excellent work with lilies and other bulbs at Arlington. Desiring to try out some of the government produced bulbs in comparison with imported Dutch stock, a letter was sent to the Department of Agriculture, asking if it would sell some for this purpose. The reply was most interesting and illuminating. "Boiled down," it simply stated that all surplus bulbs with two small exceptions had gone out in the regular Congressional distributions! But, that perhaps, at some future time, some might be for disposal.

(Continued on page 52)

Hardy Roses For the Garden

ALEX. CUMMINGS, JR.

THE first important detail in the outside culture of the rose begins in the location of the rose garden. Choose, if possible, a location that is somewhat sheltered from sweeping winds, but not too enclosed to prevent a free atmospheric circulation. A warm, sunny position that will receive the benefit of the morning sun and is sheltered somewhat during the afternoon is the ideal location, yet the rose prefers the full sweep of the elements to the shadows of overhanging trees or nearby buildings.

The rose is not as fastidious in its preference of soils as we are frequently informed. It will give excellent results in any good garden soil that is well drained; that is, soil that is free from standing water. Making a rose bed in itself is, can never be a complete success, for no amount of drainage material can amount to little more, in effect, than a catch basin or receptacle for the surrounding water to drain into. The land surrounding the bed must be equally well drained.

In preparing the bed, the soil should be excavated to a depth of eighteen inches or two feet, and refilled with soil, turf, and barn-yard manure in equal quantities, with the addition of a generous sprinkling of coarse bone meal.

The success of the rose bed depends much upon the quality of the plants, to begin with. It is generally conceded that the budded, two-year-old rose is the best for Eastern America. Some more experienced growers prefer to plant dormant stock, while others prefer the established pot plants that are obtained in growth for May planting. Either type is undoubtedly good, the advantage in purchasing plants that are started in pots being in the fact that there is less possibility of loss in planting. Again, it is not always possible to get the ground in shape before it is too late to successfully plant dormant stock in the limited time available. It is important that the soil be in good working condition, not dry, and yet not so wet as to be disagreeable to work with. The plants, if dormant, should be set about two inches below the part where the root and the top unite, or a little lower than previously planted. If the plants are from pots, the ball of earth surrounding the roots should be set two or three inches below the surface level. Part of the soil, only, should be replaced, well firmed and the plant thoroughly watered. When the water is absorbed the remaining soil can be filled in, firmed, and the bed raked level.

The subsequent cultivation and care required merely provides a means of relaxation to the rosarian. The soil should be cultivated lightly at frequent intervals and the plants watered when necessary. A thorough watering is far more beneficial than frequent sprinklings. An occasional application of liquid manure is decidedly beneficial, particularly if applied in a weak solution once or twice a week until the buds commence to show color, when stimulants of any description should be withheld. In early July, a mulch of any strawy material can be applied to conserve moisture and protect the roots during the heat of mid-Summer.

The majority of our garden roses will come through the average Winter without much protection, if their location is somewhat sheltered, but they are all benefited by a generous Winter covering. A heavy coat of well-dried leaves will afford ample protection to the more hardy roses, but the Hybrid Tea, the Tea, and other less hardy types require a more careful protection. We find soil to

be the best material for protecting tender roses. Where the roses are not too closely planted, the soil immediately surrounding each plant can be drawn up on it to a height of nine to twelve inches. Where the plants are closely placed, the soil should be drawn in from the compost heap or garden. The object in covering roses is not to keep the frost out so much as to keep it in the ground; winter killing is caused more by changeable weather, the alternate freezing and thawing doing more damage than any amount of severe freezing. When the protecting soil is thoroughly frozen, a covering of leaves or light litter will keep the plants in good condition until the Spring.

The majority of climbing roses are hardy under ordinary conditions, but there are occasions when some protection is desirable. In this event, the growths must be removed from their support and bent not too abruptly to the ground and covered, as far as possible, with soil. Heavy caned plants cannot be altogether protected in this way, without the risk of fracturing the more rigid growths, but they can be bent far enough to permit covering at least two-thirds of the younger wood, and this, of course, is where the protection is required with rye straw and this capped with paper heavy enough to shed the rain.

The additional trouble involved in affording Winter protection is well repaid in the plump and healthy condition of the wood when uncovered.

The most important detail in hardy rose culture—that of pruning—is one that is apt to puzzle the grower not thoroughly familiar with the various types and their habits. The quality and quantity of flowers depend to a great extent on this operation and to the grower not sure of his subject, the best advice, perhaps, would be to let it remain unpruned.

Climbing roses require very little pruning, the removal of the old battle-scarred and dead wood, or any that may appear superfluous, and trimming back the ends of any remaining wood that seems out of balance. This applies of all Ramblers, Wichurianas, Pillar Roses and the hybrid climbing varieties, such as Paul's, Carmine Pillar, Climbing Frau K. Druschki, and roses of that type.

The Hybrid Perpetual or Remontant roses with a few heavy growing exceptions, are benefited by the removal of all weak or dead wood, and pruning the remaining growths back to from three to six eyes, the upper remaining bud should point outwards whenever possible, the purpose of this being to keep the new growth away from the center of the plant.

The pruner's judgment should always be governed by the growth of the plant. If it is heavy and erect in habit, as we find it in the varieties Clio, Margaret Dickson or Gloire Lyonnaise, the pruning should be less severe. Less vigorous kinds of a more branchy lateral growth, Louis Van Houtte, Alfred Colombo, or Fisher Holmes, for instance, should be cut back hard, one or two eyes being sufficient in the lighter wood and not more than four in the heavier wood.

Hybrid Tea and Tea roses require approximately the same treatment. The strong growing kinds can be left a trifle longer, while the weak varieties should be cut practically to the ground to give the best results.

The Dwarf Polyantha and Baby Ramblers merely require a thinning out of the weak or congested center growths, slightly heading the remaining wood back.

What is a Flower?

WILLARD N. CLUTE

TO ask "What is a flower?" seems at first glance an extremely foolish question. Anybody with average intelligence ought to know what a flower is. If by the term we mean the creations offered by the florist it is probable that few would go astray in the naming, but if we get down to exact science, and ask what the botanist means by "flower" the matter is invested with more difficulty.

Are "Calla lilies" flowers? No, they are bunches of flowers. Are dandelions flowers? No, they might be regarded by the botanist as a bouquet but never as single flowers. How about the sunflowers? The case is still worse, for the sunflower is really a bouquet of two kinds of flowers. Are pussy-willows flowers? No, they are only half flowers, while the "flowers" of the flowering dogwood are a bunch of flowers plus, and so are those of the poinsettia. The "flowers" of the painted cup are colored leaves and so it goes.

Everybody knows, of course, that the seaweeds and other algæ, the fungi, lichens, mosses, liverworts, ferns and various other low forms of life have no flowers at all, otherwise there would be no distinction in calling one branch of vegetation "flowering plants." But a good many true flowering plants might be put in this flowerless list by a student unfamiliar with their peculiarities. For instance, let us take the case of *Wolffia*. When full grown the plant is about the size of a period on this page. One has to use a microscope to get much of an idea of it, and yet it is a member of the flowering plant group in good and regular standing. It is true that its flowers consist of a single stamen and carpel each, but these suffice for the plant's needs in this line for the two organs mentioned originate the pollen grains and ovules which in turn produce the sperms and eggs which unite to form new plants. This, indeed, is all that any flower is for, and though other plants may have additional parts, just as rich men may have more servants than others, these extra parts are seen to be superfluous for the plants can get along very well without them.

Wolffia is our smallest American flowering plant, but there are other and larger species with flowers nearly as simple. In the grasses, sedges, cat-tails, and the great majority of our forest trees, the blossoms are similar in structure, though there are likely to be more of each kind of organ. A great many people are surprised to know that such plants bear flowers at all. The blossoms of the poplars, willows, birches and some others are rather more conspicuous and therefore more familiar sights, but it is seldom that the non-botanist sees any connection between these and the fruiting of our forest trees. The idea held by many seems to be that acorns, pine cones, and hickory nuts just happen.

One peculiarity of these simple flowers is that the stamens and carpels are frequently borne on different plants. This is true of the willows and poplars where it takes two separate trees to produce a single ripe seed. Such species are spoken of as dioecious, and the clusters of stamens and carpels are known as staminate and carpellate flowers respectively. The last mentioned may also be called pistillate flowers, but carpellate is a better term.

In pines, oaks, walnuts, chestnuts and numerous others, the staminate and carpellate flowers are borne on the same plant but in different places. This is well seen in the common cat-tail where the stamens are above the carpels on the same stalk. After producing the pollen the

stamens fall off but the carpels remain and ripen up into the cylindrical brown mass of fruits with which we are all familiar. Maize or corn is another good example. Here the tassel consists entirely of staminate flowers and the ear of carpellate ones. When young, an ear of corn is really a bunch of flowers! Or, perhaps it might be better to say a bunch of half-flowers since complete flowers are regarded as consisting of both stamens and carpels. Again, a pine-cone is a cluster of ripened carpels. In Spring, however, the pine tree bears a second set of cylindrical, cone-like objects which ultimately open and shed clouds of pollen on the air and thus prove themselves to be staminate flowers. When staminate and carpellate flowers are borne on different parts of a single plant, the species is said to be monoecious. In addition to the arrangements thus far mentioned, various other plants may have three kinds of flowers, staminate, carpellate and a mixture of both stamens and carpels. In no case, however, is there a species of flowering plant that lacks either stamens or carpels, though as we have seen, certain individuals may lack one or the other.

In the older books the stamens and carpels are called the essential organs because both are absolutely necessary to the production of seeds. Probably a better name for these organs is sporophyll since it is now known that the pollen grains borne by the stamens and the ovules borne by the carpels, are spores. All the flowering plants must possess these parts no matter how many accessories they may have in the way of petals, sepals, coronas, nectaries, bracts, spurs, and disks. These extra parts may help the stamens and carpels in carrying on their work, but they are not necessary.

One has to go back to the ferns to understand how we are warranted in calling the so-called essential organs, sporophylls. In the ferns, it is well known that some of the leaves bear small dustlike objects which are known as spores and which reproduce the plant. Such leaves are called sporophylls to distinguish them from the ordinary vegetative or foliage leaves. In other fernworts, though the sporophylls are alike, the spores do not produce plants of the same sex when they germinate. The best nourished are likely to produce eggs and the less vigorous bear sperms. In still other members of this group there is a difference in the size of the sporophylls and a corresponding difference in the spores. The small spores produced by the small sporophylls give rise to plants bearing sperms while the larger sporophylls of course ultimately produce eggs. Thus when we come to true flowers we see the same two forms of sporophylls, a little more refined, a little more distinct, and a little more efficient, but still sporophylls. They are arranged on the flowering stem, as leaves are arranged in rosettes, and may, on occasion, turn to leaves. Indeed, it is quite likely that we have the whole matter reversed and that leaves have been derived from sporophylls or perhaps both sporophylls and leaves have originated from some more primitive form. The botanist is fond of saying that a flower is a branch beset with sporophylls, and this comes pretty near to answering the requirements. In accordance with this, however, it would seem as if some of the fernworts might qualify as flowering plants. None of these latter plants, however, bear seeds, and seeds are the really distinguishing features of that highest division of the vegetable kingdom, which we commonly call flowering plants.

My Dream Garden

FLORUM AMATOR

HAPPY is he who dreams about ideal possessions and environments, those which make life beautiful and lovely, and yet is not made miserable by the obvious scantiness of his actual possessions and the homeliness of his surroundings. Such as he may dream of a spacious garden, set amid beautiful surroundings and still not be unhappy in cultivating his own little garden plot.

My dream garden occupies about one acre on a country place. The ground slopes a little toward the south, is well drained and naturally fertile. In shape my dream garden is square. A trench three feet wide and four feet deep has been dug along the boundary lines and has been filled with rough field stone, which had been well grouted as they were placed in the trench. On this foundation a wall three feet wide and six feet high is built of rough field stone. In the center of the wall from the bottom to the top the stones are held together to a width of two feet with strong cement, and care is taken that the inside ends of the stones, which form the inner and outer sides of the wall extend into this cement and are held firmly by it, but the outer ends of these same stones are not filled in between with cement. The outer and inner surfaces of the wall, therefore, are irregular and rough with pockets here and there and shelves, for the stones forming the outer sides of the wall are given a slight upward tilt instead of being laid horizontally. The top of the wall is jagged and so holds more tightly the eight inches of strong cement with which it is finished. There is a heavy gate of non-rust metal in the center of each wall. These gates are five feet wide so that a horse and cart may enter as well as a person. In the top of the wall on each side of each gate is an urn-shaped hole about twenty inches wide and deep, thickly cemented on the sides but not on the bottom. Such is the location and the confines of our dream garden.

In the midst of this garden is a large, square open space, in the center of which there is a well that gives an unfailling supply of water. This is surrounded by a high stone curb. Over the curb there is a frame of rustless metal which supports a wheel over which passes a chain. To this chain are attached two buckets, and all are of the same metal as the frame. To the north, out of the shadow of the well, is a sun dial; to the south, a piece of appropriate garden statuary; to the east a large concrete fish basin; and to the west, a lily pond of concrete and of an artistic design.

The garden is piped with rustless iron pipes, laid below the frost line, so fully that any point in the garden is watered with the use of a twenty-five-foot hose attached to one of the numerous hydrants. Not far outside the northern wall of the garden is a windmill whose high tower of field stone is laid up in strong cement and surrounds a well. From this well a constant supply of water is pumped up into a large, stone encased, rustless metal tank on the top of the tower. The sails of the windmill are of non-corroding metal. The tank is connected with the garden pipes.

At different appropriate places in the garden are chairs, settees, benches and tables of concrete of artistic design, and pieces of beautiful statuary, but only such as are appropriate to a garden.

About two feet away from the walls a path, five feet wide, on each side of the garden. This and all the other garden paths are of gravel. All the garden beds are

dug and well fertilized to the depth of three feet or more. These beds are of rectangular shape.

Fifteen feet south of the northernmost path of the garden and extending to its most eastern and western paths is a pergola, nine feet high, whose posts and cross beams overhead are of reinforced concrete, and beneath which there are concrete benches, chairs and tables. All these are the mere physical features of my dream garden.

The life of my dream garden is in the many kinds of plants, growing not only within it, but on the sides and tops of its confines as well. On each side of each gate and corner, extending from the gates and corners about fifty feet on the outside of the walls, close-clinging hardy vines, placed in an aspect most desirable to each kind, are growing; namely, the several species and varieties of Ampelopsis, Hedera, Euonymus, and Schizophragma. Inside the gates on each hand for about twenty-five feet the same vines are growing on the wall.

At the foot of the walls, both inside and out, are growing the larger hardy ferns in positions favorable to each; the Adiantums, the Aspleniums, the Dryopteris, the Osmundas, the Dennstædtia, the Polystichums, and others. In front and among these ferns are terrestrial orchids, such as Cypripediums, Habenarias, Orchis, Liparis, Calopogons, Spiranthes, Corallorhizas, and Pogonias.

In the pockets among the stones in the outer and inner surfaces of the wall and on the little upward tilting shelves, in suitable kinds of soil which have been placed in and on them, except where there are clinging vines, small rock-loving ferns and plants and mosses are growing thickly. There are a great many kinds and species and varieties of these plants growing in the wall pockets and shelves, and they form one of the most interesting and unique features of my dream garden. In the urns on top of the walls are growing Pinus Mughus, and such other dwarf evergreens as are suitable for these locations.

At the foot of each post of the pergola are hardy vines which run up over the post and the overhead structures; Wistarias, Begonias, Akebias, Clematis, Lonicera, Aristolochia.

North of the pergola there is a path five feet wide. Between this path and the most northern part of the garden, extending from the most eastern to the most western path, is a bed eight feet wide containing choice hybrid Rhododendrons. They are protected from the Winter's drying winds by the north garden wall, and from the burning and drying sun of both Summer and Winter, by the vine-covered pergola on the south.

About fifteen feet north of the southernmost path of the garden there are two rows of reinforced concrete posts, five feet apart each way and extending from the easternmost to the westernmost paths. South of these posts, which are ten feet high, is a path five feet wide, also extending to the most eastern and most western paths of the garden. On the posts are growing the various climbing and rambler roses.

Between the path south of the roses and the southernmost path of the garden is another bed, eight feet wide, filled with Rhododendrons. The posts, which are staggered, and the rose canes on them, give the Rhododendrons considerable protection from the north winds, and the southern garden wall helps to shield them from the sun.

There are beds of tea, of hybrid tea, of hybrid perpetual, and of other classes of roses in the sunniest loca-

tions of the garden. Various kinds of flowering shrubs, all kept pruned low, are well represented and give a succession of bloom from March to November. Dwarf ornamental flowering trees at points of vantage play a prominent part in my dream garden. These trees are pruned so that they grow low and are not massed, but are set along the paths in the ends of beds of such plants as are not injured by a little shade, or are positively benefited by it. Prominent among the flowering shrubs are hardy Azaleas, Buddleias, Clethra, Colutea, Deutzias, Forsythia, Hydrangeas, Hypericums, Kerrias, Lespedeza, Magnolia, Philadelphus, Spiræas, Styrax, Syringa, Tamarix, Weigelas, and Viburnums. Among the smaller ornamental flowering trees are chiefly to be found Cornus, Halesia, Kœlreuteria, Oxydendrum, and Prunus.

There are several beds of berried and bright barked shrubs, and such trees as give late Autumn and Winter effects. There is a moderate number only of well pruned dwarf evergreens here and there.

The lily pond is well stocked with hardy Nymphæas and the fish pond with several kinds of fish.

The hardy herbaceous perennial flowering plants and the hardy lilies and other bulbous plants, and the hardy Irises are growing in numbers in my dream garden, some in separate beds and some in the edges or among the shrubbery. Indeed, all the hardy lilies, and other bulbous plants, and most of the hardy Irises, so many that we can hardly name them, are growing in this garden. Among the hardy herbaceous perennials are the Peonies, the Moutan or tree class is given unusual attention, as well as the albiflora or Chinese, and the officinalis varieties are not neglected. From earliest Spring until late Autumn some one or more of the perennials are in bloom: Alyssum, Anchusas, Anemones, Anthemis, Asters, Astilbes, Boltinias, Campanulas, Chrysanthemums in sheltered locations, Coreopsis, Delphiniums, Dianthus, Dicentras, Digitalis, Doronicums, Eremurus, Eupatorium, Gaillardias, Gypsophila, Helianthus, Hemerocallis, Hibiscus, Hosta, Convalaria, Iberis, Liatris, Lobelia, Lupinus, Lychnis, Malva, Monarda, Phlox, Platycodon, Primula, Pyrethrum, Ramunculus, Tiarella, Veronica, Viola, and Yucca.

These flowering trees and shrubs, rose bushes, pond lilies, hardy lilies, and other hardy bulbs, and the hardy herbaceous perennials in my dream garden afford me a quantity of cut flowers throughout the open season of the year.

The pretty, but short-lived annuals also find places to grow between the hardy plants here and there, and when the perennials are not in bloom, the beds and borders are still kept bright by the blooms of the annuals, Asters, Snapdragons, Verbenas, Calendulas, Marigolds, Mignonette, Stocks, and Poppies.

But imperfectly described is my dream garden, which I can see with my mind's eye and enjoy. You, too, though deprived of a physical garden such as you would like to possess, may enjoy a dream garden of your own.

NYPHÆA "MRS. G. H. PRING" PRING NEW WHITE-FLOWERED HYBRID

(*N. ovalifolia* × *N. "Mrs. Edwards Whitaker"*)

ACCORDING to commercial growers there is an increasing demand by the public for a tropical white day-blooming lily of large size. Up to the present time all tropical day-blooming water-lilies have ranged in color from pink to blue, with one exception, the species *Nymphæa gracilis*. The African species, *N. ovalifolia*, of recent introduction, has white flowers shaded with blue and pink at the apex of the petals. In 1919 experiments were started at the Garden with the object of producing the much-needed albino hybrid. Stock of *Nymphæa* "Mrs.

Edwards Whitaker" was selected as a desirable parent, in view of the pale campanula-blue flowers bleaching to pure white with age, a factor transfused through its parent, *N. ovalifolia*. The seed parent was between *N. gracilis* of Mexico and *N. ovalifolia*. Hybrids from *N. gracilis* in cultivation have not improved the offspring in size to the same degree as *N. ovalifolia*, nor has the white proved a recessive character in the second or third generations. In fact, experiments at the Garden with *gracilis* hybrids did not produce type *gracilis* or revert back to it (see *Ann. Mo. Bot. Gard.* vol. 4, p. 1). *Nymphæa ovalifolia* crosses so far have brought forth type *ovalifolia* in the second generation. *Nymphæa ovalifolia* was therefore selected as the other parent. Reciprocal crosses were made between *N. "Mrs. Edwards Whitaker"* and *ovalifolia*, producing varieties like the parent "Mrs. Edwards

Nymphæa "Mrs. G. H. Pring"

Whitaker." *Nymphæa ovalifolia* × "Whitaker" gave the desired result, producing both albino and Whitaker varieties. The best-flowered seedling showing Whitaker-shaped petals with white as the dominant factor was selected as the type flower, the foliage likewise showing Whitaker influence. This was carefully self-pollinated during 1920, the seedlings bringing forth albino flowers the next flowering season. In 1921 the finest plant was again selected and self-pollinated, producing the same type of flowers the following season. The desired hybrid was obtained by selection during three years, thus proving that the white coloration is fixed, provided of course that all foreign pollen is excluded.

It having been proved that the flowers had finally reached a stage of development superior to the white-flowered *N. gracilis*, specimen flowers were submitted to the Society of American Florists and Ornamental Horticulturists in convention at Kansas City, August 15, 1922, and the lily was awarded honorable mention. Mr. Charles Tricker, water-lily specialist of Arlington, N. J., visited the Garden after the convention, in the capacity of official judge, to report on the condition of the entire plant as growing in the pool. He stated that "the new hybrid presents the biggest one jump in the development of a new water-lily to date." The size of the flowers varies from eight to ten inches in diameter.—*Missouri Botanical Garden Bulletin*.

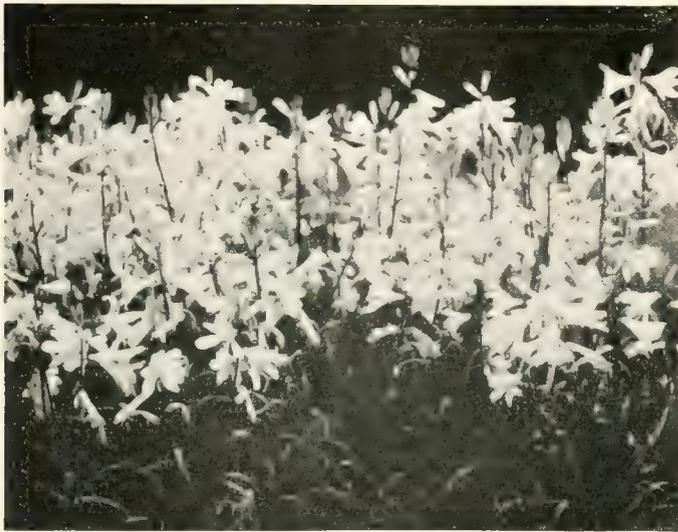

TENTH INTERNATIONAL FLOWER SHOW
GRAND CENTRAL PALACE, NEW YORK, N. Y.
MARCH 12-17, 1923

Do not overlook this important horticultural event

Anthericum

RICHARD ROTHE

CONSIDERING the great diversity in genera and species offered in hardy herbaceous plant catalogues the outsider is apt to take it for certain that he will find in modern American gardens adequate richness in variety, heightened by discrimination in selecting the material and subsequent originality in floral effects. As far as the average comes in question, I am afraid, in the main, we fail to come up to reasonable expectations. In looking over the contents we find ourselves confronted with a remarkable sameness both in plant material and its arrangement. Granted, we employ species of merit; we give proof of our sensitiveness in regard to harmony in color combinations, but after all, we remain loath to avail ourselves of anything beyond the well known traditional lines.

Anthericum liliastrum giganteum

This self-confinement to a very limited number of species deprives us more or less of our opportunities to exert individual ingenuity. The garden owner, as amateur, looks to the horticulturist for practical leadership and the rank and file of the latter apparently lack ambition. Certainly, we have as exceptions here and there—gardens testifying to the mastership of their originators in handling and taking full advantage of the present wealth of beautiful plant material at our disposal. These are examples which at a glance show the thorough familiarity with the practical growing part of designer and caretaker; examples testifying to an innate love for the work done. Without those qualities we are bound to fail. Love creates the enthusiasm necessary for extraordinary results; the experience as growers keeps us aware of the limitations set by the cultural requirements of plant species. Practical knowledge alone safeguards artistic ingenuity from indulging in mere fantastical exploits, which, as utter failures, bring discouragement, blocking our road for advance. Object lessons of this kind demonstrating the present need of experience in the field of practical growing are by no means rare.

At a recent visit to one of Philadelphia's most advanced herbaceous gardens your correspondent had the pleasure of enjoying the attractive old-time picture of a few clumps of *Anthericum liliastrum*, the well known St. Bruno's lily. The narrow grass-like foliage and the long spikes of small white flowers, sweetly fragrant, awakened in the beholder's mind vivid reminiscences of the past. We have

lost sight of this garden inmate of bygone days and are delighted to see it again. Similar impressions are gained when we find ourselves confronted with plantations of the St. Bernard's lily, *Anthericum Liliago*. But both species, of late, have been by far eclipsed by *Anthericum Liliastrum giganteum*. This new giant form of the old St. Bruno's lily, bearing stately spikes of large white flowers, resembling miniature Madonna lilies, represents one of the choicest materials for the refined garden of today. Plantations of the size shown by our illustration possess an irresistible charm. Perfectly hardy, a rather light, but well enriched soil with ample drainage is essential for thrifty growth. For northern districts the open sunny exposure is a necessity. In the Middle Atlantic States light partial shade seems to prolong the flowering season during June and early July. *Anthericum Liliastrum giganteum* may be raised from seed sown in early spring. To a limited extent we can propagate by division of the root-stocks. Leaf-covering during Winter will prove the best material for protection.

WHAT TO DO WITH FROZEN PLANTS

IT is safe to state that not a Winter passes by without a number of plants being destroyed by frost. Pot plants in particular, many of which could undoubtedly be saved did their owners know what to do with them when King Frost holds them in his icy embrace.

In order that we may better understand the treatment of frozen plants, it will be wise to briefly consider what happens when frost reaches them. The liquid contents of the cells become frozen and expand, the cell walls are ruptured, and the plant's tissues in general are disorganized. It is now a fairly well-known fact that a plant whose cells contain only a comparatively small amount of water will stand, without injury, several degrees more frost than a similar plant whose cells are turgid with liquid; therefore it is excellent practice, as a preventive of injury by frost, to keep plants as dry as possible without injury during the Winter months.

But supposing a plant or plants have been badly frozen, what are we to do to save their lives? The whole answer is given in three words, viz., thaw them slowly. It has been proved over and over again that if a plant is thawed sufficiently slowly, the cells are able to once more absorb their contents that have been displaced by expansion, and the plant is little the worse for the disorganization that has occurred. If it is a window or room plant that is affected, stand it in a very cool corner where the temperature is only slightly above freezing point, and keep it there until it has thawed.

The occupants of cold frames are often badly frozen, and if a sudden burst of sunshine is allowed to reach them much damage will be done. Keep the mats or other covering over them until a slow or gradual thaw takes place. But it is when the whole of the occupants of the greenhouse, owing to some defect in the heating arrangements, become frozen that the most destruction is likely to occur, and prompt measures must be taken if any of the plants are to be saved. As soon as such a condition is noticed, take care that the heating apparatus does not right itself and thus send up the temperature quickly. Then cover the glass with thick mats, straw or other shading material, in case the sun comes out and

(Continued on page 42)

The Bog Garden

ARTHUR SMITH

COMPARATIVELY few people are aware of the multitude of charming plants which make their home upon peaty bogs. As it is useless attempting to make purely bog plants to grow, or at all events really thrive anywhere else, we must, if we desire their enjoyable company, create an environment suitable for them.

Superficially considered, there may not appear much difference between the requisites for a bog garden and a water garden. There is, however, a specific distinction which requires to be emphasized before we can thoroughly understand the principles underlying the construction of artificial bogs.

Many plants known as aquatics, or semi-aquatics, will grow in a bog, but no true bog plant will thrive as an aquatic. If a natural bog is examined, it will invariably be found to be composed of sphagnum moss and a black peaty substance, floating in water more or less deep, although perhaps touching the bottom at the edges, and a portion of this material on, or in, which the plants are growing is always raised above the level of the water. Thus, while part of the roots of some of the plants may reach the water below, nearly all of the plant itself is growing above, not in, the water, and if the water rises then the medium in which the plant rests, rises with it. Therefore while the bog plant is always living under conditions of perennial and abundant moisture it is never actually in the water.

In a swamp there is always more or less drainage in the sense that although water may be continually running in, it is also continually running out, and the swampy medium is closely in connection with the soil below. In a true bog drainage is practically non-existent, and there is invariably an underlying stratum impervious to water. Bogs are generally found in holes unconnected with running water, and they very frequently are found on mountains and alpine situations; in fact there are quite a number of alpine plants which are denizens of bogs.

From the fact that water does not flow or soak through a bog, bog-water is always more or less acid and dark-colored. This is a condition which is peculiar to bogs and which is not found in places where the water is always moving forward, even if slowly, and it is suitable to the existence and growth of certain fungi which are necessary to the life of many bog plants.

These fungi are really microscopic plants and they live in association with the roots of other plants, digesting their food, or at least most of it, for them. This association of root and fungus is technically known as mycorrhiza, and in Nature, bog soils are known to have a large number of mycorrhizal plants growing in them; that is, plants which will not thrive without the existence of their special root-fungus. It is worthy of note that many trees, shrubs and other plants living on upland soils, also exhibit mycorrhiza. There are two classes of mycorrhiza, one which penetrates the cells of the roots, known as endophytic, and the other known as ectophytic, in which the fungus invests the root with a covering of mycelium the threads merely coming into close contact with the root cells without entering them. In both cases, especially in the latter, the reason for allowing as much of the medium in which plants are growing to remain on a plant's roots when transplanting is indicated, and also explains the fact that there are many plants which will never survive the operation of removal to another place unless their roots are kept covered with the moist

medium in which they have previously spent their lives.

Actually, comparatively little is known of the delicate and complex relationship between the mycorrhizal habit of obtaining food used by bog plants and the acidity of bog water, but experience has shown that such relationship exists.

Natural bogs have been many hundreds of years reaching their present condition and their being where they are presupposes an underlying stratum impervious to water, therefore in constructing an artificial bog a water-tight bottom must first be secured.

Of primary importance is, of course, the position, and where there is an undrained area in a hollow, the problem almost solves itself. In such a case all that is necessary is to excavate the ground to a depth of not less than two feet, to any extent available or that may be desired, place a layer of puddled clay to make the basin surely water-tight and then put in the soil mixture as described later on. Where there are no naturally suitable sites and in dry situations a bog garden may be made by forming a basin and lining it with concrete a foot thick over which should be smeared an inch or two of puddled clay not only for the purpose of making it absolutely water-tight, but also to counteract the action of lime contained in the concrete.

The size and form of such garden may be varied at discretion. While it is important to secure informality, as with all other natural gardens, one must guard against the stiff, or regular, informality which sometimes places the brand of artificiality over gardens of this kind. A visit to a natural bog, and the observing of its lines and characteristics will be very helpful to those contemplating the formation of a bog garden which will be artificial, but which it is desired at the same time to appear natural. Obviously the best material in the way of soil to use is that from a natural bog taking everything as it comes, with as much bog-water as possible, for which purpose barrels are the best things to move it in. When this bog-muck cannot be obtained a mixture may be made of leaf mould, commercial peat, wood-earth scraped from the surface, under oaks preferably, together with the twigs and leaves from the forest-floor, so that the mixture as a whole will form a spongy mass.

Irregularly-shaped mounds and ridges should be formed rising a foot or more above the water level. This not only gives a more natural and pleasing contour but affords a greater planting surface from a given area, and creates conditions for plants preferring to be more raised above the water than others; also plants can be better displayed than when the surface is entirely flat. Rocks to act as stepping stones may be placed at convenient intervals to enable one to walk about the bog, to see the plants and perform any work required connected with them.

When a piece of naturally swampy ground is chosen for the site of a bog garden it will be sure to have a crop of more or less coarse, water-loving plants, such as Cat Tails, Rushes, Sedges, and the like, growing on it. These must first be thoroughly eradicated root and branch, otherwise they will only work harm among and ultimately kill out bog plants.

A bog garden should not be formed in a position likely to be affected by storm-water, preferably it should be where water sufficient to take care of evaporation only should ooze or trickle into it. Effort should be made to

keep the bog just full enough not to overflow, so as to enable the whole material, which if properly constituted will be like a sponge, to remain thoroughly saturated, but at the same time no water should run out, otherwise the essential acids which are the life of purely bog plants will be lost.

Small pools of open water should be provided for in a bog garden for the purpose of growing the very interesting little plants known as Bladder-worts. These are different species of *Utricularia*, they have small purple and yellow flowers, some float on the surface and are supported by air-bladders, others root near the edge of the pool. They are the most delicate of all bog species. These bladders are also traps for supplying the plant with animal food; they have a valve-like door through which insects enter but cannot get out, and their substance is used as food by the plant. These bladders are most numerous and effective in connection with species living or floating in stagnant water.

With the exception of these open pools, the first step after getting the soil into position is to cover the whole with live sphagnum moss, this will soon take root and when once established will make a delightful carpet in which many of the plants will grow without being planted in the soil; other plantings may be made by pushing the moss aside and replacing it around the plants. This covering of moss also prevents evaporation and keeps roots cool.

As before stated, the reason for having a bog garden is that in it many very interesting and beautiful plants can be grown which would not thrive or even live in any other situation. Those who have seen any real natural bogs and who have studied the plants inhabiting them must realize the wealth of material that is worth while bringing into our gardens.

A bog garden is desirable even for the Insectivorous Plants alone, especially for those examples of the existence of brain-power in plants, the Sun Dew, *Drosera rotundifolia*, found in bogs all over the world, and the Venus Fly Trap, *Dionæa muscipula*, which Linnæus called the "Miracle of Nature." Then there is the queen of the peat bog, the Snowy Lady's Slipper, *Cypripedium spectabile*, the grandest of all our many beautiful native orchids. If this plant were native of a foreign country and could only be obtained at considerable expense, special conditions suitable for it would be created in many gardens for the sake of having it. Our native family of orchids contains many other charming plants and they are all for one reason or another worth growing, and, with only one or two possible exceptions, they will all thrive in bogs.

Curiosities like the Pitcher Plants, *Sarracenia*, and the lovely *Menyanthes trifoliata*, with its exquisite, wax-lake pale pink flowers, have both their homes in bogs. Altogether as William Robinson wrote "Conservatories of Beauty" are to be found, sometimes covering hundreds of acres, in natural bogs.

The following is a list of some of the choicer bog plants, some of which have already been mentioned: *Arethusa*, *Calopogon*, *Calla palustris*, *Calypso*, *Cypripedium*, *Dionæa*, *Drosera*, *Habenaria*, *Lewisa*, *Lilium parviflorum*, *Lophiola*, *Menyanthes*, *Narthecium*, *Ophoglossum*, *Primula parryi*, *Pyrola*, *Pogonia*, *Helonias*, *Sabbatia*.

When the area of a bog to be dealt with is extensive, or if outside the artificial bog garden the ground is more or less swampy and perennially moist, there are many worth while plants too coarse and rampant for the bog garden proper, which will revel in those conditions, and which will beautify such situations to a greater extent than the natural growth already existing, although some

of the latter will invariably be found to be worth retaining. In any case, and when the bog garden is constructed with dry ground surrounding it, it should be tied to landscape by suitable plantings. Also some tall growing subjects should be used on the outside of the bog garden to afford shade which some bog plants desire.

Among the shrubs suitable for swampy places may be mentioned, *Rhodora canadensis*, *Rhododendron vicissum*, *Kalmia angustifolia*, *Chamædaphne calyculata*, *Ledum groenlandicum*, *Andromeda polifolia*, *Cornus sanguinea*, *Magnolia glauca*, *Clethra alnifolia*, *Vaccinium corymbosum*, *Vaccinium macrocarpum*, *Ilex verticillata*, and *Neopantes canadensis*.

Of herbaceous perennials liking wet ground the following are among the most showy: *Acorus calamus*, *Calla palustris*, *Iris pseudoacorus*, *Asclepias lanceolata*, *Osmunda regalis*, the herbaceous *Spiræas*, *Trillium*, *Hemerocallis*, *Lobelia*, *Myosotis palustris*, *Lilium*, *Parnassia*, *Symplocarpus Veratrum*.

When the soil conditions outside a bog garden are of the ordinary dry character any of the usual shrubs and perennial plants may be used to create conditions which harmonize and connect with the landscape.

JAPANESE BARBERRY

IN any list of the most popular shrubs, the Japanese Barberry (*Berberis Thunbergii*) would undoubtedly appear near the top. It's not a one-merit shrub but, on the contrary, possesses so many desirable features, is appropriate in so many different positions, that it well deserves the popularity evidenced by the demand for it.

First of all, the foliage and its arrangement, or habit of growth, is attractive. This attractiveness is not confined to a week or two, as is the case with so many flowering shrubs that win us with their bloom, but is present from early Spring until Autumn. In the latter season its crimson foliage holds us and this is followed by the scarlet berries so striking that even the printers of Yuletide cards now reproduce them, perhaps as an innovation over the timeworn Holly. Nor are these berries of the sort whose fleshiness soon succumb to frosts and are discolored.

With massing in the foreground with taller shrubs, the Japanese Barberry fills the bill. Its low spreading growth is desirable for use in this position and its small foliage ties in with the turf where a large leaved plant would appear bold or too much of a contrast. Its value as a foreground plant for evergreens should not be overlooked, not so much as a permanent plant—for it often becomes too large and will encroach upon the slower growing evergreens—but the protection its spiny branches afford in turning away canines; also children who might otherwise brush against the evergreens. For use in this manner it is well to keep the Barberry cut away from the evergreens lest the lower branches of the latter die off from crowding. If cutting back the Barberry is not favored another method is to transplant the plants away from the evergreens or replace with smaller specimens, the latter really making the best proportioned grouping as seen in newly planted masses.

For foundation planting the Japanese Barberry is one of the best plants to use on account of its low growth, well furnished base and all season attractiveness. The latter is especially desirable where the planting is close to the house and always conspicuous. Japanese Barberry, in connection with brick work, whether it be as base planting of a house or along a wall, forms a harmonious Winter combination, the red bricks, scarlet berries and brown branches blending most effectively.

—*Florist's Exchange*.

In the Garden and in the Greenhouse

GEORGE F. STEWART

IN writing these notes, I may quite often write from the standpoint of ideal conditions. My readers must keep in mind that unless help that has had experience in garden and greenhouse is provided, along with modern equipment in both departments, there may be difficulty in carrying out some of the suggestions.

A garden is a big subject to think about, and in the carrying out of what one has in mind and what can be done with the equipment and help available, is the reason why many of us fall down. If one has an imaginative mind (and I plead guilty), a gardener is very apt to attempt things that are impossible to carry out, unless one has an unlimited supply of means. High cost of living and the fast growing tax rate has hit many once famous gardens hard, and if I read the signs of the future of gardening correctly, the days of the large garden and great ranges of glass houses are past, except occasionally.

Mankind will, I believe, always have a garden. It seems to be inherent in the nature of him, as travelers tell us that among the most uncivilized tribes, crude attempts at gardening are noticeable around their more permanent abiding places. Is it the backward longing for a lost Eden? Why not look the other way to "That City that hath foundations, whose Builder and Maker is God"? The word picture of it in Sacred Writ is strangely like a Glorified Garden, and that longing for an ideal garden, which I find in me, sees there its realization.

The garden in Winter, especially if it is more natural than formal in outline, has a beauty all its own, even in a month like the past January, which has been a record breaker for depth of snow and lack of sunshine. Occasionally, when the sun has come up in the early morning, the bold outlines of some of the larger deciduous trees, with patches of white snow clinging to their branches and the carpet of snow underneath make an impressive picture which city dwellers do not often see.

In a winter, like the present, evergreens and shrubs gives the gardener a great deal of anxiety. Damp snow, in spite of all his efforts, has anchored many branches flat to the ground, especially if these storms are followed by a quick sharp frost. By trying to release them quite often more harm than good is done. It is often better to let them alone, until Nature loosens them from the ground. If the bush seems out of shape, before the sap begins to ascend, put a stake with a crotch under each branch. If this is done, invariably they will come back to their former outline with very little loss of branches or flower buds. In dealing with Nature the gift of patience is a great asset.

During February and early March, it is better to take advantage of every good day and get all pruning of fruit trees done. I am a great believer in Summer pruning, but the majority of us have very little time to attend to it then. The principal idea in pruning is to preserve the natural outline of the tree and encourage fruiting wood, also to prevent overcrowding of the branches. If shape and spacing of the branches are taken care of, so that when the tree is in full leaf sufficient light penetrates to the centre, Nature, as a rule, will form plenty of fruiting wood. The advantage of Summer pruning can be readily seen when it comes to shaping a tree. The foliage is fully developed, and open spaces between the branches are more easily seen when it comes to thinning out the

more crowded parts. The cut over parts also heal more quickly. If a fruit tree is fully developed, and in good shape on the top, and does not seem to fruit well, generally the trouble will be found at the roots. Tunnel under the roots and give it a good root pruning. Cut over all strong woody roots, using judgment as regards distance from the trunk, according to the size of the tree. Immediately under the tree operated upon, a strong tap root will generally be found that has penetrated into the sub-soil. This root may be cut-back quite hard. Root pruning is better to be done in the Fall, but no great difference will be noticed if done quite early in Spring.

If fruit trees outdoors have become badly infected with scale insects, another spraying may be given now. A spraying in the Fall and another in the Spring is usually practiced, but a third will help to clean neglected trees far quicker. After every storm, a walk should be taken all over the grounds, and a sharp look made for any damage done to any of the trees. If any limbs are broken the jagged ends must be at least cut even, and smoothed over and painted. The entire branch may be better to be cut close to the main trunk if no decent breaks are behind the broken part.

Look carefully over all the shrubs for scale and attack them right away with the usual scale remedies. The common lilac is one of the worst for San José scale, we find, and complete eradication seems impossible.

All flowers and vegetable seeds necessary for the coming season are now better to be in stock, especially if one is quite a distance from a reliable seed firm. Tools of all kinds should be examined to see if any repairs are necessary and old worn out ones replaced. Our Spring season here in the East is short, and all these small things attended to now will save much time later on when the soil is fit to be worked outdoors. If one has no room in the greenhouse, and has plenty of frames available, many of the smaller growing vegetables may be grown in them. A hotbed mixture of manure is necessary for this work. Good horse manure for this is more difficult to get every year, making it all the harder for the willing and ambitious gardener to have such vegetables as carrots, beets, spinach, lettuce, dwarf beans, etc., at an early date. A row of early peas may be sown along the top of frost-proof frames, but this is only advisable if the family is small, unless the frame space is extensive.

Sweet peas should be sown now in small pots, two or three seeds to a pot. They can be thinned down to one after they germinate. A cold frost-proof frame is the best place for them, as they thrive all the better if sturdy and strong from the beginning.

Sow early cabbage and cauliflower; Brussels sprouts need a long season to mature, and should also be brought along in a cold frame so that nice plants may be available to set out when the season opens outdoors. An early batch of celery is also in order, also egg plants, peppers, and tomatoes.

Mushroom beds may also be made up for a succession. This crop depends on a good supply of horse manure in a condition that can be used for mushroom growing. Of late shavings and other refuse from lumber yards have been more used than straw for bedding horses, and other fungus growths rather than *Agaricus campestris* are likely to annoy one if droppings are gathered from a stable where that material is used for bedding. There is some difference of opinion as to what temperature one should

introduce the spawn into the bed, but if the spawn is good, around 75 deg. is generally safe. A building where the temperature can be kept close to 53 deg. will be found best to produce the crop. We have seen excellent crops under a carnation house bench. Keep the beds moist but not in a soggy condition. Mushrooms are always grown in the dark, yet we have seen an excellent crop, as mentioned above, under a greenhouse bench which was by no means shaded. The other day I picked four excellent specimens on a bench among *Antirrhinums* and *Calendula*, where no spawn to my knowledge was ever introduced. Furthermore, throughout the British Isles large quantities used to be gathered in old pastures when I was a young fellow, and all the darkness they received was during the night. I wonder if any experiments have been tried along this line. The best specimens we ever saw were grown in a cellar under a barn that had large cellar windows. The beds were always made in a rather rough and ready manner. The manure with all the straw in it was put in just as it came from a nearby horse barn, in the old days of horse cars, moistened down with a hose, and left until the temperature fell to 80 deg., after which the spawn was introduced in the usual way. A large pile of manure was always left near the door and the steam evaporating from it was always more or less condensing over the beds. The gardener there was keen on exhibition work and I remember the mushrooms being shipped from Boston to Philadelphia Spring Exhibitions. The size and texture of those mushrooms attracted considerable attention there. One exhibitor, who was in the commercial line and had been having it pretty much his own way, as a successful mushroom grower, was beaten that time. He did not like it very well, and flung out at my boss that his specimens were not shipable mushrooms. With a quiet grin Davy said, "That's strange; I shipped them from Boston by American Express a day ahead of myself."

Sometimes, very early in March, if one has a piece of well sheltered land facing south, peas may be sown outdoors. I have done this when the ground was quite moist; in fact, I find from my note book, that in 1921 we sowed peas, spinach, carrots, beets, and parsley on March 9, and on the ends of the rows, we broke the frosty lump to finish the lines. There was one piece of ground, about three yards long, that was quite lumpy with frost. However, the seed was sown and the lines completed. I naturally watched the development of the crop on that frosty piece, and could see no perceptible difference in the rows either in germination or growth. That year we picked peas, beets and carrots on the 9th of June, grown entirely outdoors. One of my neighbors beat me by two days.

If one has stored a good stock of rhubarb roots they can be easily forced under a bench in the greenhouse. Asparagus is a vegetable that forces easily, four to five year old crowns are best for this purpose. This necessitates a great deal of labor, time, and foresight. Box in a space under a greenhouse bench that is run around 60 deg. A six inch board will be about right, and pack in the required number of roots with soil covering them about three inches deep. Where a supply can be kept up, batches may be brought at intervals of three weeks.

Onions that were started for exhibition purposes about January 1st should all by now be potted off. Some of the best growers around here plant them out of 3½-in. pots, which means they receive two pottings. The leek is another exhibition vegetable that should now be started.

After March comes in, good cold frames can be freely used for the more hardy plants that are to be used for bedding purposes. Care, however, must be taken that they have ample covering for any cold night that comes along.

IN THE GREENHOUSES

The greenhouses, by this time of the year (late February and early March), will be quite gay with many Spring flowering plants. Some of the acacias and other Spring plants that are intended for Spring shows the latter part of March, will have to be kept quite cool. A little shading will not be amiss if they show signs of being on the early side in flowering.

Carnations are now flowering freely, and as the sun gets stronger, with heavy firing, red spider will soon gain a foothold if the plants are neglected. Select a bright day for watering the benches, and at the same time give them a good syringing in the early part of the day. Clean water properly applied under pressure is the best thing I have found for that pernicious insect. A little stimulation with sheep manure and Clay's Fertilizer alternately, will help the carnation plants from now on. The benches, if they have done well, will be well filled with roots, and with frequent waterings will leach out the plant food more quickly.

The rose house by this time will have quite a good deal of blind wood and thinning out a little of it will encourage stronger breaks. Roses are very hungry plants and can use up plenty of food in variety. They also like plenty of water syringed on the plants and at the roots, especially if they are grown on shallow benches. Every bright day early in the forenoon, they should receive a good syringing and once a week, at least, some plant food.

Primulas are now flowering nicely, and a little plant food once a week will help to keep them agoing. *Cinerarias* are also in vigorous growth and some of them will now be flowering. Those intended for exhibition will have to be kept quite cool. Waterings with soot water will bring out the colors with added brilliancy.

Amaryllis, or *Hippeastrum*, will not need attention. As soon as they show signs of flowering, remove the loose soil from the top of the pot and give them a top dressing with a good loam, that has been enriched with bone meal and Clay's Fertilizer. A good light bench in a temperature around 55 deg. at night suits them well. When in flower, a slight shade will prolong the flowering period. Feed them well with liquid manure and water when they get into vigorous growth.

Erlangea tomentosa has been flowering all the Fall and continues with us throughout the Winter on a shaded bench. We find that the color does not bleach out when kept in the shade, and on this account, its lavender blue flowers are always favorites. Keep young rooted cuttings moving along as they require it. *Erlangea* does well planted out on a bench. When cut, the flowers keep better if placed in warm water.

Do not neglect any cuttings of *Buddleia asiatica* that have been rooted. After *Stevia* has gone past, this valuable plant, we find, is the best for taking its place, both as a plant and for cutting. It can be kept in bud for a long time in a cool pit and brought in in batches.

For anyone looking out for a fine flowering specimen plant in Summer *Stephanotis floribunda* is one of the best. It looks well trained on a balloon trellis, and is one of the freest flowering plants we know of. Pot in a good rich, fibrous loam and give it greenhouse treatment, that is, a temperature around 50 deg. The house we have it in is an old style one with plenty of wood in it, and we never shade it in Summer. I have no doubt but that a modern house would have to have a slight shading in Summer. *Stephanotis* used to be one of the worst plants to keep clear of mealy bug, but since the advent of Hydrocyanic gas, we have no trouble keeping it free from this insect.

The genus *Hoya* has a few varieties that also make excellent Summer flowering plants, *Hoya carnosa*, *H*

imperialis, and the beautiful, shrubby, *H. bella*. They grow well in a good turfy loam in a greenhouse along with *Stephanotis*. From November until February they need to be kept rather dry to ripen their wood for flowering.

Secure cuttings of such plants as *Acacia*, *Boronia*, *Bauera*, *Eriostemon* and heaths at this season, which root readily in a propagating bed with a bottom heat of about 75 deg., keeping the top from 45 to 50 deg. Azaleas, now that they are denied admittance, can be rooted in the same manner if the wood used is not too hard. In about three years they will make nice small plants. It is very interesting to watch the development of seedling Azaleas if one has the time to devote to it. Any gardener visiting around Boston in the Spring should pay a visit to Holm Lea, Prof. Sargent's place in Brookline, Mass. Mr. Sanders, his gardener, is a master hand at raising seedling Azaleas and has some fine varieties of his own raising.

Camellias may be rooted the same as the hard wood plants noted above. They are now flowering freely and care must be taken that they don't get too dry at the roots. They flower best in a night temperature of 45 deg. Bougainvilleas may now be brought along in heat. Keep them well syringed and tie them into whatever shape is most pleasing to those that enjoy them when in flower.

Early plants of *Clerodendron Thomsonæ* (probably better known as *C. Balfouri*) may now be started into growth in the sunniest part of the tropical house. If they are not thoroughly ripened off, that is, if the old leaves are still clinging to the twining wood, take them into some shed, away from the greenhouses and give them a good whiff of sulphur fumes. One will be astonished how even they will break into eyes all over last year's growths after this treatment. They can be had in flower in about eight weeks by giving them a night temperature of 65 deg., running it up during the day to 85 deg.

Sow an early batch of Queen of the Market asters; also antirrhinums, *Tagetes* and *salpiglossis*. Small seeds sown on the top of sifted sphagnum moss without covering them, we find, do much better than when covered with sifted loam or sand. The fungous growth, called damping off among gardeners, we have never seen if sphagnum is used.

Some of the early flowered calanthes will be showing signs of starting into growth. It is advisable to shake them out, and repot in fresh soil before the young growths send forth roots, as the young roots are likely to be damaged in the operation. They grow well in mixture of the fibre of loam, sphagnum moss, and a third of dried cow manure. Keep them shaded, near the glass, in the warmest corner of the tropical house.

By the end of February the orchids will have to have a thin shade over them. If one has not roller blinds, we find that a very good shade can be made with a couple of table spoonfuls of white lead to two quarts of kerosene oil and spread evenly over the glass. This mixture lasts well and is easily removed. I would on no account use linseed oil in the mixture as it is very difficult to clean off the glass.

Dendrobium nobile will now be flowering, and when they have finished, repot any that require it, also remove any shriveled up back bulbs. They like to make their growth in a humid tropical heat and only lightly shaded. They ought to be carefully watered until the young growths are well up, for if moisture gets into them one is certain to lose them. The same holds true of *Dendrobium Phalænopsis Schroderæ*. Dipping is the best method of watering these plants as one can keep the water well

away from the growths. We find also that both these *Dendrobes* respond to feedings with weak liquid manure after they emit roots from the young growths. We use a handful of hen manure to three gallons of water, preferably rain water once a week, and alternate with the same amount of Clay's Fertilizer.

The early vines will now be setting fruit, and syringing should be discontinued until a good set is secured. A night temperature around 65 deg. should be maintained, rising to 80 deg. during the day. There is some difference of opinion about stopping the shoots ahead of the fruit, we practice three joints and allow laterals to run out so that all the glass is covered. After the fruit is set, we always give the border a sprinkling of Clay's Fertilizer or Thomson's Vine Manure and point it in. I think it is a good thing to keep the border as loose on top as possible by frequent stirrings. Of course, care must be taken that roots are not broken.

Let pot fruit come along naturally. In forcing for early use try to imitate natural conditions as much as possible at this season. High temperatures will result in ruin, and on the other hand, draughts from cutting wind, from ventilators must be avoided.

Peaches and nectarines should be thinned down to about three hundred fruits to the tree, less would be better. I refer to a tree with about nine feet of spread on each side and about nine to eleven feet in height.

Keep up a succession of melons if one has plenty of space. No one, however, should attempt melon growing in Winter, unless they can command a night temperature close to 70 deg. and, furthermore, there is also some difficulty in setting the fruit, which must be done by hand.

FROZEN PLANTS

(Continued from page 39)

causes a sudden thaw. After these precautions have been taken, secure a good supply of very cold water and syringe the plants, pots, staging and glass with it until the whole are drenched. This will cause a very gradual thawing to take place, and many plants will be saved. Leaves will probably be lost, and the plants will need several weeks to recover from the shock; but better this than a total loss.

Half-hardy plants growing in sheltered positions out of doors are often ruined by the removal of the protecting material as soon as a thaw sets in. Such protection should be left on until all signs of frost have gone from the plant under notice. If such a specimen has had no protection before frost occurred, much good might be done by covering it with mats after it is frozen but before it thaws. — *Exchange*.

DYNAMITING HOLES

Years ago there was a veritable craze for dynamiting holes for apple trees, and the dynamite companies boomed this method of hole preparation as being simple and inexpensive as compared with digging them in the regulation manner. This method of hole preparation is still being practised and is necessary to break up certain kinds of hard pan and very retentive loam. Hardly an apple grower in New England now practises it. The fruit men find that while apples and other fruits in dynamited ground made tremendous growth for two or three years, at the end of six or seven years, trees planted in holes dug out in the regulation way were superior. The Arnold Arboretum of late has adopted dynamiting its holes and finds the labor cost to be much less. It will be interesting to note how the growth of trees and shrubs in these holes a few years hence will compare with the undynamited ones.

RELATIONS BETWEEN GARDENERS ON LARGE ESTATES AND NURSERYMEN

(Extracts from a paper read before the New England Nurserymen's Association at its convention held in Boston
by Robert Cameron.)

THE text of my subject is taken from the Gospel according to St. Matthew, Chapter 7 and verses 1, 2, 3 and 5. Please give special attention to the words and I know if you do, you will be better men when you leave this room.

1. Judge not that ye be not judged.
2. For with what judgment ye judge, ye shall be judged and with what measure ye mete, it shall be measured to you again.
3. And why beholdest thou the mote that is in thy brother's eye; but considerest not the beam that is in thine own eye?
4. Or how wilt thou say to thy brother, let me pull out the mote out of thine eye, and behold a beam is in thine own eye.
5. Thou hypocrite, first cast out the beam out of thine own eye; and then thou shalt see clearly to cast out the mote out of thine brother's eye.

Is it not true at this time that one fact stands out clear and undisputed, that after centuries of teaching and preaching, crime and immorality and downright dishonesty and hypocrisy are more plentiful than at any other previous time in our history? This is not only true of our own country, but of practically every country in the world. There isn't a single day one takes up his newspaper but one reads of the most horrible crimes, scandalous thieving, grafting and blackmailing. Is it not time that we asked ourselves, "What is the cause of all this devilment?" The only way to get at the facts is to try and get back to the cause. There is no lack of churches, schools, Sunday schools and every imaginable kind of sect and creed to make people good and help them to live upright lives. Yet you will see at once from my previous statement about the condition of things in the world that the work done for centuries by the institutions I have mentioned have failed in their endeavor. Why have they failed? The answer is simple and not far-fetched. We are all hypocrites. We are not doing or have not done what we promised to do.

To most of us our religion has been one of one-day-a-week. Most of you believe, undoubtedly, in keeping one day holy and go to church on Sunday. The other six days your Sunday religion is forgotten. What we need is a religion that is good for seven days a week and 365 days a year.

The Fourth Commandment that was handed to Moses is no good for the present times. It says, "the seventh day you shall keep holy." It ought to be revised and to read,—Seven days shalt thou keep holy and do nothing on any day that you would not do on Sunday.

I have read of 40,000 Odd Fellows parading our streets in Boston, 100,000 Masons, 75,000 Knights of Columbus and many other organizations. Many of you here undoubtedly know the solemn obligations these men take. Ask yourselves, do they keep their obligations? If they did live up to what they promised, My! we would have perfect conditions here. That number of upright men would soon change the conditions of the world.

The curse of the world at this time is selfishness and greed, and we are just as bad as others. For a dollar we will sell our reputation. The curse of our country is the almighty dollar. The poor man gets more happiness out of the world than the man who has nothing in his mind but always chasing the dollar. Did you ever know of anyone to take a dollar with him when he left this world?

By this time you are wondering why I have taken up the subject you assigned to me in this manner. I have

tried to point out to you that we are all weaklings and have our shortcomings and that there isn't much good in any of us.

The subject you assigned to me is—"Relation Between Gardeners on Large Estates and Nurserymen." I am not my brother's keeper, consequently I am not responsible for his actions. Undoubtedly you know much more about gardeners than I do and what I will have to say will be mostly my own experiences and observations.

I might say that I do not consider nurserymen better than any other class of men. I have found some of them honest and some of them dishonest. Neither do I consider gardeners to be any better or any worse than the average man. One thing I would like to say and that is, that there is ample room for improvement in both classes of men if all the stories that are heard are true. I will also say this, that of all men, gardeners and nurserymen should be the least susceptible to evil doings. Their work is amongst Nature's most beautiful productions, consequently their thoughts and deeds ought to be bigger and better than the ordinary man in his occupation.

One thing I would like to impress upon you and that is this, that all gardeners are not dishonest, that there are many good and upright men in the profession. There are some black sheep in every flock.

On a large estate the gardener has in many cases from one to three millions of dollars' worth of property under his care. There are large expenditures and he has the handling of a lot of money during the year.

It would interest some of you, I know, to hear of some of the temptations that are thrown in the way of a man in charge of a large estate. I hope you will forgive me for giving my own personal experience in dealing with gardeners, because I have never been in business and never sold a plant in my life.

(Mr. Cameron here related some of his experiences with tradesmen, but he never fell to temptation.)

One must always remember that the man who gives commissions is just as guilty as the one who takes it. If a man gives it because others give it, he is no man at all that will not stand up and denounce this mean habit. In the long run he would be better off if he denounced it.

There is only one way to get rid of this practice and you men know the way just as well as I do, but I think you haven't the courage or the backbone to do it. The only way to abolish this practice is for the trade to discontinue it. If you will not pay commissions or indulge in even worse offences, than the gardeners can not be participants in this evil doing.

To me there is no occupation like gardening and anything you can do to make it cleaner and better I shall be glad to give you any assistance that is in my power. But first of all make up your minds that you are willing to give up this custom of giving commissions and there will be a quick death to this detestable habit.

At the conclusion of the reading of the paper an interesting discussion followed. The *Boston Herald* in reporting the convention said, "Robert Cameron of Ipswich, retired president of the National Association of Gardeners, spoke on 'Relations Between Gardeners on Large Estates and Nurserymen,' scoring the practice of offering gratuities to secure sales. His address was so effective that the gathering immediately proposed an amendment to the by-laws of the association, providing that 'any member of the association found guilty of giving a gratuity to a gardener, or other person, shall be prosecuted by the association and be expelled from membership.'"

It was proposed to invite the National Nurserymen's Association and the American Seedsmen's Association to follow the action taken by the New England Nurserymen's Association.

Foreign Exchange Department

A DWARF HORSE CHESTNUT.—The North American Horse Chestnut (*Esculus parviflora*), or American Buckeye, is a most distinctive shrub, or low tree, and one which would be more widely planted were it better known. In this country it grows to a height of some six feet to ten feet, with a wide spread of branches and the noble foliage which is common to most of its race. Above the copious leafage the white, sweet-scented flowers, with their red-tipped stamens, rise in erect, pyramidal clusters in August, so that an established specimen, or group of them, makes a most charming and effective picture in open woodland or on the lawn. This is a most desirable Horse Chestnut for gardens of moderate size, and its late-blooming habit will appeal to many. It is also known as *Pavia macrostachya*.—*The Garden*.

THE ALPINE CATCHFLY.—An indispensable occupant of almost any rock garden, however small it may be, is *Silene alpestris*. It is consistently free-flowering, and so easy to grow that the merest tyro in the culture of Alpines may embark upon its cultivation if possessed of a little rockery, or even if that is not available it may be attempted, with every prospect of success, in the front of the mixed border, where the soil is not too heavy. It is a charming little dwarf plant of slender growth, with pretty leaves, and giving in abundance from May to July a succession of its beautifully-formed glistening white flowers. In cultivation *S. alpestris* appears to like a moderately light soil, but it is not too fastidious, although it does not flourish well in stiff clayey soils. Loam and peat or leaf-soil with a good dash of sand seem as good a compost as one may have. Its height is given by as many as three inches, but it is sometimes a little more. It is always neat, however, and is such a pleasing subject and blooms so satisfactorily that it ought to find a home in every rock garden. It is increased by division, and can also be raised from seeds, which are best sown in pots in light soil and placed in a frame or cool greenhouse.—*Gardening Illustrated*.

HYPERICUM CORIS.—Here we have one of the choicest gems of the rock garden, albeit one which is generally easy to please. Sometimes, in our colder localities, it suffers sadly in certain Winters, yet, as a whole, it is hardy. It is one of our most precious St. John's Worts, and one which writers on alpine flowers never tire of praising. It has delicate little stems, which serve to carry its exquisite leaves of bluish-grey, which in their arrangement and general appearance remind us of some of the Heaths. On these, again, are borne the star-like flowers of good size and of a charming tone of pale gold, the whole plant, especially when of good size, having an elegant and chaste effect. Those who know it in its native habitats, especially in the Southern Alps, wax eloquent over its charm as they see it there in clouds, as it were, and showing its grace and loveliness in a manner we cannot hope to enjoy in the limited space of our gardens. Save for its liability to suffer in severe Winters in certain places, it is hardy, but it is not generally known that it is naturally a limestone plant, though not invariably so. It is more plentiful by far on the limestone formations. It is pre-eminently a plant for the rock garden in a sunny place.—*Gardening Illustrated*.

A "BLUE DAISY" FOR THE ROCK GARDEN.—There are several so-called "Blue Daisies" for the rock garden, none of which is either a Daisy or blue. *Erigeron leiomerus* is the best and prettiest of them all, a delightful, thrifty little plant, forming compact carpets of narrowish leathery leaves half an inch high and carrying in May or June a generous crop of lavender blue Daisy flowers on stiff, erect stems only two inches high. It is like a tiny, very dainty edition of *Aster alpinus*. It grows sedately but steadily, forming neat mats. After a year or two in one place *E. leiomerus* is apt to grow leggy—in its small way—but an occasional top-dressing soon remedies this, or the plant may be dug up, pulled to pieces and transplanted.—*The Garden*.

STANDARD ROSES.—In choosing a standard Rose one would favor a young plant; that is to say, a specimen budded last year and grown in the nursery this. Such have youth and vigor, and I should regard one that has been in the ground longer, and may be cut back a season or two as faulty, even if it had a fairly bushy top or head. Plants or trees like this which have been hanging about in the ground so long rarely do well when replanted. If I selected a Briar, one that is young-looking, if in reality comparatively thin, would be favored as being likely to furnish my future standard—a tree that would last. This would be a greater consideration even than the size of the head of growth. When planting there is a small item easily forgotten. This is at once to stake the tree. When the stem is secure there is a chance given for the roots at once to start into new growth, but if swayed by the winds tiny rootlets become injured, and thus we lose time. A standard Rose may be deeply planted. The roots of the Briar

should be just covered, trod firmly, and they obtain all the advantages of surface soil. A form of standard out of the ordinary is a variety with a climbing habit of growth worked on to a tall Briar. Such furnish splendid objects in isolated positions, and are trained by tying in the points of long-flowering shoots made the previous year to the standard stem.—*Gardening Illustrated*.

SOME MUSK ROSES.—That delightful Himalayan Briar *Rosa Brunonii* should be in every collection of Rose species. It is a prodigious grower and profuse bloomer when established. There seems to be some confusion with these Rose species. I always look upon the variety known as *R. polyantha grandiflora* as a near relative to *Brunonii*. In any case, both are worth growing. As with all the Musk Roses, huge panicles of bloom are a feature of *R. Brunonii*, and the pure white flowers with profusion of yellow stamens have a simple beauty all their own. Closely allied to this is one *Mme. d'Arblay*, a semi-double white, and also a rampant grower. The wood is apt to suffer in a hard Winter. A grand variety of the Hybrid Musks that every lover of single Roses should possess is *Miss Florence Mitten*. I know of no Rose that so persistently holds its blossoms, and the large Apple blossom pink flowers remind one of a glorified *Alexandra Day* Rose. Unlike the others I have named, it is a more compact grower and blooms right down to the ground.—*The Garden*.

A FINE MOCK ORANGE.—To those who know only the common form of the Mock Orange, *Philadelphus Virginalis* is a revelation. This is the largest flowered of its race. The blossoms are semi-double, nearly three inches across, and a cold, snowy white. In the purity of their whiteness and the compactness of their form, they might be likened to a double white *Camellia*, and the large, unusually deep green foliage tends to increase that similarity. The characteristic fragrance of the Mock Orange is, however, almost absent in *P. Virginalis*—an omission for which some may have cause to be thankful. This plant will succeed in any average soil, and is generally deemed a hardy, easy-tempered shrub that most people can plant with every confidence of success.—*The Garden*.

BUTCHER'S BROOM.—I have just had given me by a friend, who brought it from her garden at Bridgwater, a branch nearly two feet long of this uncommon shrub. It is covered with its bright red berries from top to bottom. The dark green cladodes, with the bright red berries about the size of large peas, are most attractive. I have seen this many times, but never so thickly set with berries, no doubt due to the very hot Summer of 1921. It grows well under the drip of trees, and seldom attains more than two feet high. I have the spray in a glass against a high wall, and purpose allowing it to remain there to see how long it will last.—*Gardening Illustrated*.

ACONITUM ORIENTALIS.—It is a plant certainly worth including among our hardy plants for its neat, sturdy habit, unusual color and great freedom of flowering at the end of Summer. The height does not exceed two feet, while the much branched stems bear foliage remarkably like that of the *Delphinium*, and terminate in short close spikes of pale yellow flowers. It will succeed in practically any soil and is not particular as to situation, for we have seen it rendering a splendid account of itself in partial shade, as well as in positions fully exposed to sunlight. Indeed, there can be no doubt that it prefers the latter but—at the same time—it is a plant to note where shade is fairly heavy with, however, the proviso that it is not overhung by trees.—*The Garden*.

COLCHICUM AUTUMNALE.—Though not the choicest of *Colchicums*, by any means, this is a very useful species for massing, and as it increases rapidly, it soon makes a good show. I saw a large drift of it recently in a country garden bordering a drive through some thin Beech trees, and it made quite a carpet of bright color. The soil, which was rather light and sandy, seemed to suit it admirably. The drawback to these Saffrons is the large, rather coarse foliage in the Spring, which is not very pleasing, especially when it begins to go over. With this and other *Colchicums* it is necessary to be on the lookout for slugs when the buds appear, as these pests are very fond of nibbling off the tips.—O. C. C.—*Gardening Illustrated*.

Department of Book Reviews

OLD-TIME GARDENS, by Alice Moore Earle. The Macmillan Company, New York.

Presented anew, in attractive form, is this delightful book, which though nearly a generation old, is, in its ideals of what constitutes the charm of gardens, fully modern; good taste is leading us back to the tried and the really satisfying. The author felt, for example, that "an ideal flower garden must be an enclosed garden,

homes are not made for passers-by." Quite modern is the cordial appreciation of species of flowering plants also whose superior and dependable merits have gained proper emphasis only within the past few years, notably the peony and the iris.

But the main worth of the book lies in its telling so entertainingly a wonderful amount of flower lore. In the chapter given to Sun Dials and Herbs there has been gathered together apparently all worth-while that has ever been written by the poets and the learned upon these subjects. The author's acquaintance at first-hand also with the old gardens of the New England colonies, their contents and connections of all kinds and the legends clustered around them is large. Nice discrimination is revealed by the choice of the pictures, too, and by their composition. They number about two hundred and twenty-five.—F. B. M.

THE HOME VEGETABLE GARDEN, by Ella M. Freeman. The Macmillan Company, New York.

This second in the series of "Genial Little Books About the Out-of-Doors" well deserves rank along with the editor's own volume on the Apple Tree, by which the series was so fittingly introduced. The book is not the findings of a person who has merely scratched the soil and then rushed off to print. It consists of uncommon good sense resulting from interested and intelligent experience by which even the beginner might learn to garden successfully and even to make the most satisfactory use of the products. Particularly valuable for the novice is the advice, interjected at proper points throughout the work, about fertilizers for the vegetables, a subject that very much has needed simple treatment in these times, when the old-fashioned and most reliable form is so hard to find.—F. B. M.

PLANT MATERIALS OF DECORATIVE GARDENING, by William Trelease. Published by the author, Urbana, Illinois.

Of thin pocket size this manual is designed to aid the students of botany in a field to which in the schools few of them have little introduction, if any at all. For the landscape gardener or planter it offers small use other than to aid him also in identifying the most common materials of his art by their stems or leaves or the general structure of their wood and pith. The working of the key is explained at the start so that the person familiar with the principal terms used in distinguishing plant forms, if he employs the glossary and in case of doubt checks up with the aid of the index, should as a rule have no difficulty in classifying and naming, even without attention to their flowers, 1,159 distinct kinds of trees, shrubs and herbaceous plants used in ornamental planting in the eastern part of the United States and in Northern Europe. Compactness has barred out all but a very few references to the availability of any plant in landscape design.—F. B. M.

AMERICAN PLANT NAMES, by Willard N. Clute, Joliet, Ill.

The book is a compilation of every known common name under its proper genus and species, with the correct common name indicated, as *Kalmia*: *K. latifolia*, Mountain Laurel, American laurel, calico-bush, small laurel, wood laurel, spoon-wood; ivy, big-leaf ivy, ivy-bush,—clamoun (poison ivy). There is to follow an abundantly cross referenced index which will enable the investigator to find any name in its proper place at once. The work is issued in parts at fifty cents a part, and there are to be about seven parts. The area covered is the northeastern states.

Brief Horticultural Jottings

The fact that *Bouvardias* when propagated from root cuttings are likely to show variations in color was pointed out by George F. Stewart in his greenhouse notes. Double flowered varieties have also been known to revert to singles when propagated by this method.

New Jersey's agricultural department hopes to produce a blue-berry one inch long. Millions of Americans reading that will look back to days when they used to pick huckleberries smaller than the tip of their little finger, bending over to reach the bushes, a few inches high.

How rich the human race would be if it would confine its energies to getting wealth out of Nature and the generous earth, instead of one man trying to get it from his neighbor, or one nation from its conquered enemy!

Plans are rapidly perfecting for the early distribution of one *Rose Mary Wallace* and probably two of the new *Dr. Van Fleet Hybrids*, to be introduced by the American Rose Society who at present is co-operating with the Department of Agriculture for this purpose. Any firm, wholesale or retail, desiring to make application for these, should write for terms at once to Robert Pyle, President American Rose Society, West Grove, Pa.

Apples without cores or seeds are promised by a discovery announced at Abbotsford, Canada. According to the announcement a seedless and coreless variety of *Fameuse* apple has been developed which differs but slightly in shape from an ordinary *Fameuse* by being longer and flatter at the ends, but with the typical coloring and flavor. Except for a slight marking on the flesh which outlines the situation of the core in an ordinary apple, there are neither core nor seeds.

The apples were developed in an orchard at Abbotsford and the discovery that they were out of the ordinary was an accident. They had come from a new block of *Fameuse*, about eight years old, bearing for the first time in market quantities.

That plants grow more quickly by moonlight than by sunlight is now being demonstrated at the Hartley Botanical Laboratories of Liverpool University. The research followed the remark dropped by a gardener named Hayes Swanley of the Horticultural College to Miss Elizabeth Semens of Liverpool University that cucumbers grew two or three inches more in the moonlight than by daylight and the seeds germinated better under the moon.

Miss Semens began experimenting and in the last six weeks has made considerable progress by artificial light. She finds that the polarized light of the moon gives a spurt to seed germination and that polarized artificial light has a similar effect. Miss Semens says that moonlight can be polarized only during certain phases of the moon. She finds that when seeds are exposed in tanks of water to the direct action of the moon germination is greatly quickened. When there is no moonlight she exposes starch grains to polarized artificial light and finds that they break down, producing little masses of dextrin and sugar crystals. She says the outer skin of the leaf acts as its own polarizing apparatus and it is believed that we may be on the eve of learning what occurs within the leaf itself.—*New York Herald*.

Wild flower gardens make good sanctuaries for birds and bees, which are often in danger of starving to death through the wholesale cutting of wayside weeds. I hope to see all the Audubon societies of America interesting themselves in wayside gardening, making waste places to blossom as the rose, that they may become perpetual feeding grounds for bird and bee and thus protect our growing crops, which are everywhere being destroyed by hungry birds and bees.—A. V. G.

The item in the last issue of the *CHRONICLE*, extolling the virtues of hot laundry soap as a cure for the poisoning caused from handling *Primula obconica*, prompts me to ask for the name of that particular brand of soap.

I am one of the unfortunates who cannot touch any part of this plant without suffering for several days after from a crop of watery blisters, no matter whether in a perspiring state or as "cool as a cucumber" when the contact is made. I shall admit, however, that the resulting itch is much more annoying the warmer one gets. Bathing with good hot soapy water was tried once and it did produce an effect, but it was something akin to an electric shock, which impelled an ungainly attempt to dance. Sponging with alcohol (before prohibition) would give temporary relief, but sugar of lead solution is the best remedy in my experience thus far. The strangest thing of it all is, that previous to ten years ago, I could handle this plant with immunity.

In this connection there is one plant the name of which I shall always remember. It is *Laportea gigas*, a tropical plant closely related to the common stinging nettle. Some years ago my bare arm came into contact with the spiteful plant, and a violent throbbing immediately began under the affected arm, accompanied by a feeling of nausea which lasted for several minutes. Relief was obtained by the free use of alcohol (outside application only) and for several days white blotches showed where the fierce, stinging hairs had bitten.

H. E. DOWNER.

National Association Of Gardeners

Secretary's Office, 286 Fifth Ave., New York

1923 Convention, Pittsburgh, Pa. (Date not decided.)

The aims of the association are to elevate the profession of gardening by improving conditions within it.—To cement a closer bondship among all engaged in, and interested in, gardening—to create a greater confidence between employer and employee

Co-operating with the Massachusetts Agricultural College, the association conducts a course in training young men for the profession, whereby they obtain theoretical knowledge as well as practical experience.

OFFICERS 1923

President JOHN BARNET, <i>Sewickley, Pa.</i>	Vice-President WILLIAM GRAY, <i>Newport, R. I.</i>
Secretary M. C. EBEL, <i>New York, N. Y.</i>	Treasurer MONTAGUE FREE, <i>Brooklyn, N. Y.</i>

TRUSTEES (For 1923)—Thomas W. Head, D. L. Mackintosh, Arthur Smith, New Jersey; Robert Cameron, Massachusetts; Andrew L. Dorward, Rhode Island.

DIRECTORS—(To serve until 1924) William Hertrick, California; George H. Pring, Missouri; Robert Weeks, Ohio; Thomas Wilson, New York; Harold Bryant, Connecticut; Harry Cartwright, Michigan; H. Ernest Downer, New York. (To serve until 1925) George Wilson, Illinois; James Stuart, New York; William Kleinheinz, Pennsylvania; Edwin Jenkins, Massachusetts; Carl N. Fohn, Colorado; Joseph Tansey, New York; John Tonkin, Pennsylvania. (To serve until 1926) Alexander Michie, New York; George F. Stewart, Massachusetts; Theodore Wirth, Minnesota; George W. Hess, District of Columbia; R. P. Brydon, Ohio; William C. Rust, Massachusetts; Charles Schrahl, Wisconsin.

Dick, Clayton Mark, Mrs. Julius Rosenwald, Mrs. F. W. Upham. *Minnesota*—Mrs. Chester A. Congdon, F. H. Stoltze. *Iowa*—Mrs. G. B. Douglas. *Missouri*—August A. Busch, Dr. George T. Moore. *W. Virginia*—Mrs. Arthur Lee. *Georgia*—Asa G. Candler, Jr., G. Gumby Jordan. *South Carolina*—Robert S. McBrat.

LOCAL BRANCHES

NEWPORT, R. I.: Andrew L. Dorward, chairman; Frederic Carter, secretary

ST. LOUIS, MO.: George H. Pring, chairman; Hugo M. Schaff, secretary

NASSAU COUNTY, L. I.: James Duthie, Oyster Bay, chairman; John McCallister, Oyster Bay, secretary

BOSTON, MASS.: Robert Cameron, Ipswich, chairman; W. N. Graig, Weymouth, secretary

WESTERN PENNSYLVANIA: Manus Curran, Sewickley, chairman; Henry Goodband, Sewickley, secretary.

WESTERN PENNSYLVANIA BRANCH

A meeting of the members of the above Branch was held in the Carnegie Library, Pittsburgh, on Jan. 16th. There was a good attendance considering the inclement weather. It was proposed that the National Convention shall be held on Aug. 14, 15, 16 and 17, if suitable arrangements can be made. John Barnett, President of the National Association, outlined a few plans regarding the convention which were enthusiastically received. A committee was formed to make inquiries regarding accommodations at hotels, a suitable convention hall and report to the secretary. A vote of thanks was extended to The H. G. Heinz Company of Pittsburgh, who are known throughout the world for their famous 57 varieties, for their kind invitation to visit their plant and partake a special luncheon put up by the company. This invitation is extended to

the Convention to come in a body. John Jones was appointed a delegate from this branch to attend the meeting held in the Herbarium Room, Pittsburgh, on Jan. 17.

The following applications for membership in the National Association were endorsed by this branch: Jas. Moore, West Park; Jas. E. Murphy, Sewickley; Robt. Ladner, Swissvale, Pa.; Geo. Brownhill, Pittsburgh; John Fornoff, Pittsburgh. The next meeting will be held on Feb. 20 at the Carnegie Library, Pittsburgh. All members and friends interested are cordially invited to attend.

HENRY GOODBAND, Sec'y.

NEW MEMBERS

Sustaining Members. Mrs. Robert Bacon, Westbury, L. I. (Alfred Reoch, superintendent); Frank B. Black, Mansfield, Ohio.

Active Members: R. J. Cruickshank, Rosslyn, Va.; Colin Aitchison, Greenwich, Conn.; Chester E. Greenwood, Scranton, Pa.; Sidney Paynter, Niles, Ohio; G. W. Peterson, Plainfield, N. J.; James E. Murphy, Sewickley, Pa.; James Moore, George Brownhill, John Fornoff, Pittsburgh, Pa.; Robert Ladner, Swissvale, Pa.; Eric Gerle, Augusta, Mich.

AMONG THE GARDENERS

A farewell party was recently tendered John W. Baxter, for twelve years superintendent of the Houghton estate, Dartmouth, Mass. Mr. Baxter has accepted the commission to lay out a large new estate at Huntsville, Ala., for Miss Eva McCormick, daughter of the head of the American Harvester Co. Mr. Baxter was presented with a handsome gold watch by the men in his employ on the Houghton estate. Mrs. Baxter received a traveling bag and a purse of gold. In addition to filling the superintendency on the Houghton estate, which he laid out, Mr. Baxter filled at the same time positions as chief of police of Dartmouth, chairman of the building committee, chairman of the finance committee, chairman of the Fellowship Group of the Friends' Meeting on Smith's Neck, Scout Master of the Smith's Neck Boy Scout Troop, and Deputy Commissioner of the Boy Scouts of America.

Joseph Winsock recently resigned his position as gardener on the estate of Mrs. W. D. Guthrie, Locust Valley, which position he had held for the last four years.

Walter Harris, formerly of Madison, N. J., has accepted the position of gardener to Mrs. W. A. Roebbing, Trenton, N. J.

James Barnett has been placed in full charge of the Asa G. Candler estate, Atlanta, Ga. Mr. Barnett was formerly in charge of the greenhouse range.

If any reader knows the present whereabouts of George M. Barton, formerly superintendent of Darlington Farms, the McMillen estate at Ramsey, N. J., he will confer a favor by informing the secretary.

MEETING OF BOARD OF DIRECTORS

President Barnett announces that he will call a meeting of the Executive Board, comprising the Trustees and Directors of the association, in New York, during the week of the Tenth International Flower Show in March. Due notice will be sent to the trustees and directors of the exact date and place of meeting as soon as they have been decided on.

CONVENTION NOTES

It is expected that plans will be well under way for the annual convention, which will be held this year at Pittsburgh during the middle of August, when the Western Pennsylvania Branch of the association meets again on the 20th of the month. The chairmen of the various committees will be announced, and it is hoped that the headquarters and meeting place of the convention can also be determined. Members of Pittsburgh, Sewickley, and vicinity, are manifesting keen interest and enthusiasm, and are going to leave nothing undone to make the Pittsburgh convention an event long to be remembered. President Barnett feels very much encouraged over the outlook as he has already received numerous letters from members in different parts of the country, stating their intention of attending, thus assuring a representative body of the association at the next annual meeting.

THE TENTH INTERNATIONAL FLOWER SHOW

Those who have not secured the final schedule of premiums to be awarded at the Tenth International Flower Show can obtain a copy by making application to John Young, Secretary, 43 West 18th St., New York City. Everything indicates that the show will be the most successful as well as the most interesting and instructive of any show yet staged. The Garden Club of America is taking an active part so that the social feature will not be overlooked. It is said that the lay-out of the show this year will be different in character from the past shows. Judging from the entries already received, there will be no lack of interest in the competitive classes. Small exhibits will be as welcome as the large ones, and if you enter only one, you will be doing more than he who fails to enter at all. The show manager, Arthur Ferrington, one of our members, should have your support.

LOCAL SOCIETIES

NASSAU CO. HORT. SOCIETY

The monthly meeting of this society was held on January 10 in Pembroke Hall. President James Gladstone occupied the chair. John Hess of Locust Valley and James McManus of Glen Cove were elected to active membership; one petition for active membership was received at the meeting. The dinner committee reported progress, and that the dinner will be held at the Commodore Hotel, Glen Wood, on January 25. The exhibits of the evening were judged by Ben Sutherland, William Carter, and Joe Boehler. President Gladstone presented the Stumpp and Walter Cup to James McCarthy, for a fine collection of vegetables at the Mum Show. The exhibits for the February meeting will be 50 violets, 6 sprays of stocks, and pot or pan of narcissus.

ARTHUR COOKE, Cor. Secy.

TUXEDO HORT. SOCIETY

The annual meeting of the above society was held on January 3. The following were elected as officers for 1923: President, William Ellings; vice-president, Anton Nelson; treasurer, Duncan MacGregor; secretary, James Davidson. Executive Committee: David MacIntosh, Joseph Tansey, Ezra Wilson, Thomas Lyons, John Livingstone. The annual reports were read, and routine business transacted.

JAMES DAVIDSON, Secy.

TARRYTOWN HORT. SOCIETY

The above society held its 22nd Annual Banquet on the evening of January 9 at the Florence Inn. As usual the weather was rough, but nevertheless sixty-five members and friends came together and a merry time was enjoyed by all. Robert A. Pattison of the Tarrytown National Bank was toastmaster, Daniel J. Cashin, one of the wittiest men in Yonkers, the Rev. W. F. Irwin, Ernest F. Griffin, president of the village of Tarrytown, and Charles D. Millard, supervisor of the town of Greenburgh, were the speakers. Former Senator Charles P. McClelland was unable to be present on account of illness and for the same reason, F. R. Pierson, one of the society's strongest backers, was obliged to be absent for the first time. The Westchester Male Quartet gave several fine selections. They led the gathering in the singing of old and new songs and made the evening a very jolly one. The gathering was welcomed by Thomas Wilson, president of the society, who briefly outlined the work of the society for the past year. T. A. Weston of the Florists' Exchange was the first speaker and in his talk, he said that the Tarrytown shows are second only to those held in New York City, none of the other shows in the country equal them, and certainly none surpass them. Westchester and Fairfield Society was ably represented by William J. Sealey, William Smith, and George W. Strange. After the songs had become exhausted, the party broke up about twelve o'clock, the guests saying that they hoped they never would see the time when they would refuse to accept an invitation from the Tarrytown Hort. Society.

WILLIAM GRAHAM.

WESTCHESTER AND FAIRFIELD HORT. SOCIETY

The monthly meeting of this society was held at Greenwich on January 9. By the manner of the members and the questions that were brought before the meeting, the year 1923 bids to be a banner year. It was

Ideal 30" mower cuts a 30 inch swath and mows from 6 to 7 acres a day

Ideal Junior cuts a swath 22 inches wide. Capacity from 3 to 4 acres a day

ONLY frequent cutting and rolling will produce that smooth, carpet-like effect seen in well-kept lawns. Ideal Power Lawn Mowers do both in one operation at less than one-third the cost when done by hand.

An unskilled man at laborer's wages may be safely trusted to operate the simple, fool-proof mechanism. He will cut from a half to a full acre an hour, trimming the borders closely and rolling the open spaces to velvety smoothness. The moderate cost of maintaining a park-like lawn is obvious.

Illustrated descriptive literature, prices and valuable information on the care of lawns will be mailed upon request

IDEAL POWER LAWN MOWER CO.

AXFIXO The Superior Nicotine Dust

KILLS aphids, thrips, white fly, mealy bug, red spider, acacia scale, leaf-hoppers, ants, cucumber beetles, and most soft bodied insects. AXFIXO is a highly volatile nicotine dust evolving pure nicotine gas when exposed to the air. This gas envelopes the entire plant. It goes where liquid sprays and smoke cannot possibly go.

Packed in 1, 5, 25, 50, 100 pound containers.

Ask your dealer for AXFIXO, if he cannot supply you, write the manufacturer, mentioning your dealer's name.

Water Lilies Thrive From North To South

Tricker's Water Lilies grow luxuriously and bloom freely from Canada to Mexico, proving their ability to meet all conditions of soil, sunshine, soil and water.

My 1923 Catalogue

features hardy Water Lilies for large estates, tender varieties for tubs and artificial pools, with aquatic plants for borders and screens. Write for a copy.

WILLIAM TRICKER

Water Lily Specialist

664 Forest St., Arlington, N. J.

very apparent that the die-hards must have been either overwhelmed or absent.

It was decided among the members present that the society should hold a Fall flower show which will be on more elaborate lines than any previously held in this vicinity.

T. J. Bulpitt's resignation as corresponding secretary was read and received with regret, and Andrew Kneukes was unanimously elected to succeed him.

The society's medals for the highest number of points for exhibits at meetings during 1922 were awarded as follows: For flowers, Wm. Smith, silver medal; H. F. Bulpitt, bronze medal; for vegetables, James Linane, silver medal; H. F. Bulpitt, bronze medal.

Judging by the merits of the exhibits at this meeting for the monthly prizes from the A. N. Pierson and John H. Troy fund, competition will be even more keen than in the past.

Reports for the past year and flower show were received from the secretary, George Hewitt, and treasurer, James Stuart. A rising vote of thanks was given them for their work and the splendid reports made by them, which showed the society to be in good financial standing and very creditable to the officers in charge.

The profits from the September Dahlia Show which was held in the Y. M. C. A., Greenwich, in co-operation with the Greenwich, Rye and Riverside Garden Clubs were distributed as follows: Port Chester United Hospital, \$1,000; Greenwich Hospital, \$1,000.

The annual dinner of this society will be held at the Lawrence Inn, Mamaroneck, on Thursday, February 8th.

A very cordial invitation was extended to the members present from the Stamford Hort. Society for the members and the friends of this society to join them at their entertainment and social gathering in the Agricultural Hall at Stamford, which is the headquarters of the society, on Thursday, February 6. T. J. BULPITT, Cor. Sec.

ST. LOUIS ASSOCIATION OF GARDENERS

The January meeting of the St. Louis Association of Gardeners was held at the Forest Park Greenhouses January 4th. The meeting was presided by President John

We Are Telling It To You As She Told It To Us

"You recall that advertisement of yours, about having one of your crystal gardens so located that one could look right out the window and see the flowers a' bloom in its perpetual summerland, regardless of whether it was December or May?"

Straightway after reading it, I sent for your catalog, and looking through it slowly, leaf by leaf, lingered at the one on Page 27. Turning to the window, I looked out and saw it in my mind's eye, just as it would look.

After which you know what happened.

Looking up from my writing this, the yard is piled with snow drifts and the wind is howling like a hungry wolf, but it is perpetual summer in the bloom filled greenhouses. They are filled with flowers and I am filled with the joy of their possession."

That's what this contentment filled owner of two of our houses recently wrote to us.

Her first move to their possession was to send for a catalog.

ANDORRA NURSERIES
WM. WARNER HARPER, Prop.
CHESTNUT HILL PHILADELPHIA

Moritz, and the attendance was large.

Anthony M. Ward, vocational student at the Missouri Botanical Garden, presented an illustrated lecture on "The Use of Explosives in Gardening." Mr. Ward has had considerable experience in this phase of gardening, and his lecture proved to be of particular interest to those present, because few have had very extensive experience along this line of work. He described the use of explosives in detail, touching on the subject of the use of explosives to prepare the soil for the planting of trees, subsoiling, drainage, and the removal of stumps and rocks.

Nearly every one present took part in the discussion which followed the lecture.

L. P. JENSEN, Cor. Sec.

THE CLEVELAND HORT. SOCIETY

The above Society held its regular meeting Jan. 11th. J. M. Stevens, the newly elected president, took the chair. Regular business was transacted; two new members were elected, P. W. Popp, W. E. Marshall Co., New York, and W. E. Attwood, Johnson's Seed Store, Cleveland.

The growing of prepared hyacinths was discussed and how to get them in bloom for Christmas. It seems that the majority of the gardeners could not get them for that time and in course of discussion, it was concluded that bulbs did not arrive early enough in this section.

Carnation rust was next discussed; prevention and cure. As a preventative, spraying with lime and sulphur, 1 to 40, twice during the Summer in the field, was thought by some to be good; the use of fungicide and sulphur preparations in the greenhouse.

Iris Tingitana was another subject. Very few of the members are growing it this year, but the few who are seem to be successful with it.

The state laws on injurious diseases and insect pests, and the examination of nursery stock was brought up for consideration but was laid over for future discussion.

W. J. BRUCE, Secy.

MORRIS CO. (N. J.) GARDENERS' AND FLORISTS' SOCIETY

The twenty-seventh annual dinner of the society was held at the Mansion House, Morristown, on January 17, and, as usual, it was a notable event. The dining room was attractively decorated with roses, carnations, begonias, and other flowering plants. The program included an excellent orchestra, and local talent who rendered popular songs and some witty sketches, ably assisted by Andrew Wilson, who is always a welcome entertainer at local society functions. Charles Weathered served as toastmaster and is known as a past master of that art. Among the principal speakers were Arthur Herrington, who, as president of the New York Florists' Club, responded to a toast to that club, and Charles Totty who spoke as an ex-president of the S. A. F. and O. H. George Masson, representing the Elberon, N. J., Gardeners' Society was also one of the speakers of the evening. Edward Reagan, who retired a year ago and moved to another section of the country, was a welcome guest. As ex-secretary of the society, he spoke of its progress which at times had been through thorny paths, as well as beds of roses.

The entire object of true education is to make people not merely do the right thing, but enjoy the right things; not merely industrious, but to love industry; not merely learned, but to love knowledge; not merely pure but love purity; not merely just, but to hunger and thirst after Justice.—*John Ruskin.*

BOLENS

**Power Hoe and
Lawn Mower Tractor**

So easy to operate that boys and girls can handle it and find drudging work transformed into a fascinating and delightful play. You do not even need a demonstration to show you how to work it. Both tools and tractor are always under perfect control.

The various implements can be attached quickly and easily without the use of a wrench. Special snap hinges enable the operator to change instantly from lawn mowing to seeding and cultivating.

Descriptive circulars explaining merits in detail gladly sent upon request.

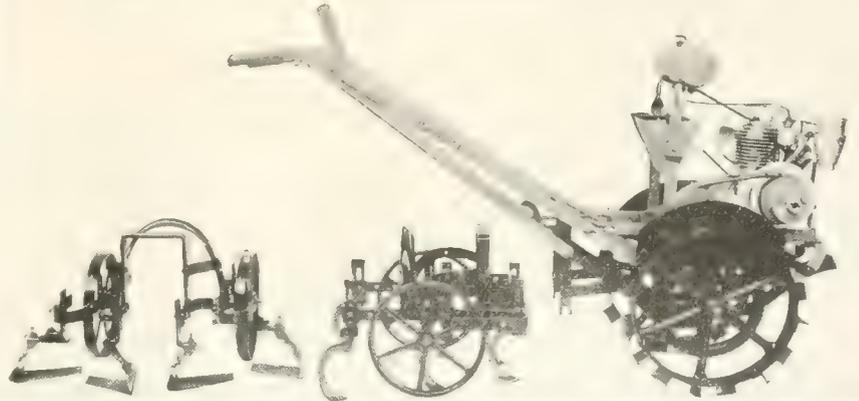

**For the Man Who Loves
ACTION!**

Here's a tool with the "PEP" and the "GO" that will delight any man looking for quick and thorough results. The BOLENS is a light tractor adapted to act as motive power for the cultivator, seeder or lawn mower. It will do many times more work than the man with the hoe or hand mower. It will go where horses cannot get and it will do a class of work that will please the most fastidious gardener.

THE FELLING OF A GIANT REDWOOD

Kenneth Craig

(Seventeen year old son of W. A. Craig.)

Noble monarch of past ages,
Towering proudly towards the sky,
Speak to us—turn o'er your pages
That we may learn before you die.

Giant redwood of the Westland,
Mightiest of this wide world's woods,
Man has come—and you must go—
A mere part of his earthly goods.

Tell us first before you leave us,
Unthinking mortals though we be,
Of marvels unfolded before thee,
Wonderful bits of history.

First, of when in bygone ages
Struggling upwards towards the sun,
Fighting always, never resting,
Until at last you won! you won!

When, as but a tender sapling
Shadowed o'er by taller growth,
Of the hardships that you suffered—
Tell us quickly—be not so loath.

You ran your race ever upwards,
Spurned by some and spurning others;
You witnessed pain, and death, and dread,
All the things the blue sky covers.

And as the years rolled ever on,
New things were born—things always new,
Earth itself was torn asunder;
But still you grew, and grew, and grew.

Years when torrents tearing downwards
Ripped the earth from round your base,
Left you hanging, still undaunted—
Conditions changed; you won your race.

Times when waters left you thirsty,
Torturing rays burned down o'erhead;
Withered, parched, but still unflinching,
Until at last your roots were fed.

Days when fire, the red-tongued monster,
Swept the vast woodlands, razing most
To Nature's gasping breast; but you
Were spared—scarred witness of the host.

Then the cold, the biting north winds
Numbed your core, you missed the pace,
But to your rescue, helpless king,
Whispered the south wind in your face.

The rains, the snows, relentless winds,
All fought you, but to no avail;
For still you stand—God's creation—
Towering over hill and dale.

Now you rest, supreme in stature,
Dwarfing others that beneath you grow,
Waving gently o'er the forest,
While south winds softly sing and sigh.

Well, indeed, you have earned your peace,
But we—vain, lust-ridden mortals—
Think only of our present needs,
So, old tree, open up your portals.

Now the glistening steel cuts deep,
Clear the sounds fall across the mart,
Deeper, deeper bite the axes—
Searching, probing out your heart.

Now the axe falls, and with fresh stroke
Why must you die, O noble tree?
You sway—sweep earthward with a crash!
My God, what fools we mortals be!

But don't blame the lumber while working—
And don't blame the saw for cutting
honey.

About This Particular Greenhouse

IT happens that only yesterday we received from our publishers a rather delightful bit of printing called "Glass Gardens," in which a complete description is given, of an exact duplicate of this particular house.

The view point is a bit different, but the plan is the same.

As companions, are four other houses of simpler design and lesser size.

Send for this new Glass Garden Circular.

Or if you prefer, send for one of us to come and talk over greenhouse possessing with you.

GUMMING OF FRUIT-TREES

If it were always possible to trace every thing to its source, it would be found that gumming in stone fruits in most cases had its origin in a deficiency of lime in the soil. Other causes doubtless may lead up to it, such as deep planting, or planting in too rich soil. Much injury is done by cropping the borders in which the choicer kinds of stone fruits are planted. The digging and manuring of the ground to meet the wants of the surface crops are sure sooner or later to throw the trees out of gear and bring on many evils, not the least of which is frequently a host of suckers, caused by the spade or fork injuring the roots, or by the manures which are used for the crops growing in the border.

It is well known to most experienced cultivators that Peaches and Apricots do best in firm soil, but if the top spit is under spade culture, the roots must go down to a lower stratum for the firmness they need, and far away from the beneficial influence of solar warmth; the growth comes late and cannot ripen properly, and is more susceptible to insect attacks. It may be thought when a young tree is first planted, that as the roots cannot occupy all the soil the border may at least be used for something until the trees require it. This is plausible reasoning, and so early Peas, Potatoes, Tomatoes, and other crops are planted, the man with the spade goes to work, and the bad system once begun is continued. Again, very few think when planting young trees that it may be necessary in most soils to mix a little old plaster or lime in some other form with the soil but to obtain clean, healthy growth, lime is an absolute necessity. Of course, on a chalk or limestone formation the natural soil contains sufficient lime for the wants of the trees, and those accustomed to note such things can tell by their appearance if the trees are getting their wants attended to.—*Gardening Illustrated.*

To be honest, to be kind—to earn a little and spend a little less; to make, upon the whole, a family happier for his presence; to renounce, when that shall be necessary, and not be embittered; to keep a few friends, but these without capitulation—above all, on the same grim conditions—to keep friends with himself—here is a task for all that a man has of fortitude and delicacy!—Stevenson.

SCHLING'S NOVELTIES FOR 1923!

You must have these in your garden next Summer

1. "INDIAN SUMMER" Schling's wonderful new, snap dragon—Rich velvety copper red, flower spikes as large as gladioli, indescribably beautiful **pkt. \$1.00.**

THINGS AND THOUGHTS OF THE GARDEN

(Continued from page 32)

Having just killed free seeds, will it be necessary next to scotch free bulbs? This is a matter worth serious consideration by the horticultural interests of the United States.

A GARDENERS' CHRONICLE reader wants to know if the writer can recommend the Rose, Gloire de Dijon, as a garden rose. I would say that I have grown it successfully outdoors in New England for over a quarter of a century. This good old rose has been in commerce for seventy years and remains one of the most popular varieties in Europe today. I well remember thirty-five years ago when filling orders for hardy roses, that every customer would insist on having "at least one Glory" put in the bundle. Although a tea, it wintered successfully with the same protection given other roses in Brookline, Mass. and flowered very persistently. A gentleman in Hingham, on the south shore of Massachusetts, classes it as one of his finest climbers and it covers a good portion of the front of his house. Abroad it is grown as a dwarf, standard, and climber; here it is best treated as a climber and laid down in Winter. I feel sure that many amateurs as well as professionals would do well with this grand old rose. The color is buff with an orange, yellow centre and the flower is large, full, and fragrant. Many firms offer it,—why not try it?

Vermont has long been noted as a state whose dairy products, turkeys, and maple syrup are of the highest quality. We all know the Green Mountain State as a delightful spot in Summer, and Winter sports have given it still further éclat. It may occasion surprise to some to

learn that the apple industry in this cold New England state bids fair to out-do the maple sugar industry in importance. At Bennington, Vt., there is now one orchard covering no less than three thousand acres with fifty-five thousand apple trees, and twenty thousand more of pears, plums, quinces and cherries. The most up to date scientific methods are used here and commencing in 1923, it is hoped to send out a train load of apples daily during the height of the apple season from this and some other Bennington orchards. Baldwin, Rhode Island Greening, and McIntosh Red are the leading apples, the red colored sorts being grown in much the greatest quantities.

The question is occasionally raised, what is the most popular rose in the world today? I would unhesitatingly plump for the Gloire de Dijon. Introduced by Jacotot of Dijon, France, as long ago as 1850, no other rose has attained such a widespread popularity. It is equally good abroad as a bush, standard, climber, pergola, for pegging down or for walls. It has buff or salmon colored flowers, and is very fragrant. Here in Massachusetts it will withstand 15 to 20 degrees below zero, and on the South Shore, it proves to be one of the finest climbers. This grand old rose is worthy of increased culture. Unlike our regular ramblers, Gloire de Dijon is a perpetual bloomer and has a fragrance peculiar to the teas, lacking in most of our ramblers. It is interesting to recall some of the earliest French introductions among roses; between 1840 and 1853 there were sent out such splendid sorts as Cloth of Gold, 1843; Prevost, 1842; Blairii, 1845; Celine Forester, 1840; Geant de Batailles, 1846; General Jacqueminot, 1852; Jules Margotten, 1853; and Gloire de Dijon, 1850. About all these roses are still in culture, surely a tribute to their worth.

The Insecticide of Recognized Merit for Greenhouse and Garden

APHINE is a concentrated material—mixes readily in water—efficient in its action—easily applied—free of the disagreeable odors and features of most insecticides—excellent as a wash for decorative plants.

FOR THE GARDEN—As a remedy against all sap sucking insects infesting flowers, fruits and vegetables, APHINE is most effective.

FOR THE GREENHOUSE—Applied at regular intervals (once each week or ten days) APHINE will keep plants in the greenhouse and conservatory free of insect pests.

FUNGINE—For mildew, rust and other blights affecting flowers, fruits and vegetables.

VERMINE—For worms and insects infesting the soil.

DREER'S TREE-SHAPED ROSES

We are offering an exceptionally fine lot of tree-shaped Roses with good sturdy straight stems about 3½ feet high in the choice and popular varieties noted below.

TREE-SHAPED ROSES.

CAROLINE TESTOUT. One of the most popular and valuable bedding varieties; large, full, globular flowers of bright satiny rose, with brighter centre, very free and fragrant.

CLIO. Delightful satiny-flesh with deep centre; the flowers are large, globular and borne on long stems.

COLUMBIA. Popular cut flower and a good bedder, a most pleasing shade of rose-pink and delightfully fragrant.

DUCHESS OF WELLINGTON. Intense saffron yellow stained with deep crimson, changing to a deep coppery saffron-yellow as the flowers develop. The flowers are fairly full, with large petals, great substance, delightfully fragrant.

ETOILE DE FRANCE. One of the best of the red varieties; color vivid crimson with darker shadings; very double and deliciously scented.

FRAU KARL DRUSCHKI. This is the ideal hardy white Rose, pure in color, petite in form, strong grower and remarkably free flowering; superb in every way.

GEORGE C. WAUD. A beautiful variety, possessing an entirely distinct color, a glowing vermilion with orange-red suffusion. The flowers are large, full, of perfect form and highly tea-scented.

GRUSS AN TEPLITZ. This is a Rose for everybody, succeeding under the most ordinary conditions. In color it is of the richest scarlet, shading to a velvety-crimson; very fragrant, a free, strong grower and in bloom all the time.

LADY ALICE STANLEY. Absolutely perfect in every way; form, color, size, freedom of bloom and fragrance; in color it is a beautiful shade of coral-rose, the inside of the petals shading to flesh-pink with deeper flushes.

LADY ASHTOWN. One of the freest-flowering varieties. The flowers are large, double with high-pointed centre; and are produced on long stems; color a soft rose, shading to yellow at the base of the petals.

LADY URSULA. A truly magnificent Rose. The flowers produced on every shoot are large, full and of great substance and perfect form, with high centre, from which the petals gracefully reflex; in color a delightful tone of flesh-pink, delicately tea-scented.

LA TOSCA. Beautiful silvery pink, with deeper centre; a very vigorous grower, with large double flowers and very free; a splendid bedder.

LOS ANGELES. This is, by all odds, one of the finest Roses ever introduced. The growth is very vigorous, and produces a continuous succession of long-stemmed flowers of a luminous flame-pink, toned with coral and shaded with translucent gold at the base of the petals.

MAGNA CHARTA. Bright pink, suffused with carmine; a beautiful Rose, and a strong vigorous grower; one of the best.

MME. EDOUARD HERRIOT, the Daily Mail Rose. In color its buds are coral-red, shaded with yellow at the base, the open flowers of medium size, semi-double, are of a superb coral-red, shaded with yellow and bright rosy-scarlet passing to shrimp-red.

MME. JULES BOUCHE. While not a pure white, it being at times slightly tinted with blush on the reverse of the petals, we consider it one of the best white bedding Roses.

MRS. AARON WARD. A remarkably floriferous variety of strong, vigorous, but compact growth; the flowers, which are of splendid form, full double, are equally attractive, when full blown as in the bud state; in color a distinct Indian-yellow, shading lighter towards the edges.

MRS. WAKEFIELD CHRISTIE-MILLER. As a pink bedding Rose there is none better. The flowers are large and are produced very freely; they are of a bright pink color with lighter shadings.

OPHELIA. Well known favorite, long stemmed flowers of a delicate shade of salmon-flesh, tinted rose.

RADIANCE. An ideal bedding Rose that continues to produce its large flowers throughout the most unfavorable hot summer weather; in color a brilliant carmine-pink, with salmon-pink shadings at the base of the petals.

RED RADIANCE. Identical with above except in color which is a bright cherry-red.

ULRICH BRUNNER. A bright cherry-red; flowers large and full; a good strong grower and always does well.

WHITE KILLARNEY. A pure white sport of the famous and popular Killarney Rose.

PRICE. Any one of the above varieties \$2.50 each; \$25.00 per doz.; \$200.00 per 100.

Dreer's Garden Book for 1923 also offers all the worth-while new as well as standard varieties of dwarf or bush Roses. It also offers Cannas, Dahlias, Decorative and Bedding Plants, Hardy Perennials, Hardy Vines and Shrubs, Water Lilies, Flower and Vegetable Seeds, Lawn Grass and Agricultural Seeds, Garden Requisites. A copy will be sent free if you mention this publication.

Water Lily Pools MAKE The Garden

So popular have Water Lilies become that no large garden is truly complete without them. Their brilliant, perfumed blooms, their sturdy tropical foliage, give them an attraction that few other flowers possess. The background of clear water renders them doubly effective.

Easily Grown— No Care Required

After planting no further attention need be given so long as the water level of the pool is not permitted to drop.

If you are familiar with the beauty of Water Lilies and Japanese Irises you will appreciate the illustrations in our catalog—three of them are in natural colors. Copies are supplied free to all who apply before the edition is exhausted.

WILSON'S O.K. PLANT SPRAY

Kills Plant Insects, Scale and Mildew
Used by Leading Gardeners

Bbls. \$90, 1/2 bbls. \$50, 10 gals. \$20,
5 gals. \$10

We have written of Prohibition and this Hootch-less, Bugless World,
Now we write of quarantine 37 and how it makes food for the squirrels,
For it certainly is making us nutty, say the Florists big and small,
But if the F. H. B. would recommend Wilson's Plant Spray,
They would need no quarantine at all.

MARCH, 1923

No. 3

Things and Thoughts of the Garden

WILLIAM N. CRAIG

IT is pleasing to note the increased interest in rock gardening in America. For years this form of gardening has been very popular in Europe and in Great Britain. No garden is really complete without its rockery; these are now often of considerable size, as for instance, the one at Friar Park, Henley-on-Thames. The rock garden at Kew attracts hundreds of thousands of visitors annually, and contains an enormous number of species. Very notable also is the one at the Edinburgh Botanical Gardens, many plants thrive better there than at Kew on account of the more northern latitude. At the Chelsea Holland House, and other noted shows, the exhibits of rock gardens are always one of the great features outdoors, and at earlier shows in the Royal Horticultural Society's Hall in Vincent Square, London, displays of rock and alpine subjects are numerous and interesting.

In America on account of the hot Summers, rock gardening may never attain so wide a popularity as abroad, but a marked increase in the culture of these plants is developing each year. Gardens such as Montague Free has constructed at the Brooklyn Botanic Gardens, are fine examples of how such gardens may be laid out. In Massachusetts there are fine examples on the Thomas E. Proctor estate at Topsfield, where James Marlborough has charge. Many members of the National Association of Gardeners had the privilege of seeing this garden on the occasion of one of the outings during last Fall's Boston convention. Rare and unique plants are to be found in this garden; the rocks are massive and well placed, and the rockery follows the shores of a small lake. Another notable rock garden in Massachusetts is on the Weld estate, Dedham. The layout here is a most natural one with a rocky stream, pools of water, steep winding paths and a veritable wealth of choice plants well acclimated and planted naturally. There is considerable shade from large trees here, which is an advantage for many shade loving subjects, but others enjoying more sunny exposures are inclined to damp off from the constant drip. The lilies, gentians, primulas, trilliums, and many other plants are wonderfully fine. The majority of rock plants prefer an open sunny exposure, but primulas, polyanthus, trilliums, erythroniums, and not a few others are most at home in at least partial shade.

Anyone with a very small garden can without much effort make a rockery. It should not consist of a mound of stones as some garden makers still seem to imagine. Stones should always be well embedded, pockets should

be of irregular shape. The stones used should, if possible, be old and weather beaten; the rougher and more rustic they are in appearance, the better. Soil should be porous to allow of good drainage for nearly all varieties. Formality should be avoided as much as possible. There are many plants which can be raised from seeds for use in the rockery, and a considerable variety of the more easily grown can be purchased at very moderate prices. Those who want "immediate effects" should start with such flowers as phlox subulata and divaricata, Alyssum saxatile compactum, single and double arabis, cerastiums, saxifragas, viola cornuta, campanulas, rotundifolia, and carpatica, various dianthus, arenarias, silenes, armerias, such iris as cristata and pumila, sedums, sempervivums, primulas, hepaticas, trilliums, blood roots, sweet scented violets such bulbs as snowdrops, chionodoxa, scillas, small varieties of narcissi, some of the species of tulips, and, of course, small cedars, spruces, and other evergreens. To relieve the flatness an occasional yucca filamentosa, foxglove or verbascum can be used. The amount of material available is great; there are numerous good plants not mentioned here at all.

* * *

The rock garden gives pleasure long before a formal garden can do so, for just as soon as snow passes, we can find snowdrops and other bulbous subjects, the Christmas rose (*Helleborus niger*) *Draba aizoon*, hepaticas, violets, primulas like *dentisulata* and *vulgaris*, saxifragas like *cordifolia*, arabis and other plants in flower. Until June there will be a constant succession of interesting flowers. During Summer we do not look for a floral display. While it is true that annuals are often planted in to continue the show of flowers, they have no place, however, in a true rock garden as they simply smother out the hardy subjects. Such plants as *myosotis*, double daisies, and bedding violas are permissible if planted where they will not encroach on other plants, but even these should really be omitted. The idea is to trust to hardy subjects only, and pockets of these can be planted out in Spring or late Summer. It is better not to do any very late Fall planting in the rock garden; bulbs, of course, are an exception.

* * *

The statice are coming into increasing favor in America; I am referring more particularly to the annual varieties. The well known hardy *S. latifolia* has long been a valued plant for the perennial border or rockery. The varieties *Bonduelli* and *Sinuata* are most useful

annuals and of easy culture in the open. Great quantities of dried flowers of these everlastings are annually imported by dealers in florists' sundries, and are used in artificial wreath making. The variety Suworowi makes a lovely pot plant and may be flowered from December until June. The stalks are very much branched, and the tail-like and twisted rosy red panicles which are densely crowded with small flowers are most attractive. By carefully selecting the seeds, it is possible to get a strain which make ideal pot plants, looking in the distance like densely flowered and glorified ericas. The way to secure a quantity of flowers for cutting in the Winter is by planting raised benches about eight or nine inches apart each way and by growing in a cool house. I saw two splendid benches on a private estate in Jamaica Plain, Mass., on March first which bore a perfect thicket of spikes and had been blooming since before Christmas. Arranged with *Jasminum primulinum*, yellow jonquils, and other yellow or white flowers, *S. Suworowi* is very effective. This variety comes from western Turkestan and is worthy of increased culture on private estates.

* * *

A rose which has jumped very much into favor the last two seasons is Paul's Scarlet Climber, undoubtedly the finest of all our scarlet pillar roses. It was raised by William Paul & Sons in England and introduced in 1916. It is a fine rose either for the garden or for pot culture. To succeed with it best for forcing, it should be pot grown through the Summer; then plants will carry four to twelve of the largest brilliant red flowers to a truss, almost rivaling Hadley in size. If field grown and potted, the number of flowers to a truss is disappointingly small. To anyone who wants a first class scarlet rose, which holds its color and does not fade out to a sickly magenta shade, I heartily commend Paul's Scarlet Climber. Juliet, the glorious *Pernetiana* from the same firm, is one we cannot afford to overlook.

* * *

There are general complaints from those who are growing early tulips this year, both for forcing and outdoor culture, of the inferiority of the flowers produced. An unusual number when forced, come blind, which is sometimes due to too early forcing, using bulbs not properly cured, and improper treatment as a whole. But this year both amateurs and florists are having poor results all round, and I wonder whether the Dutchmen are not becoming careless with their early tulips, and lavishing all their attention on the Darwins, Breeders, and Cottage varieties. The latter varieties are as fine as ever and each year are pushing the early types more and more to the wall. Certainly if forced bulbs do as poorly another season, and bedding ones look none too well, growers will be justified in gradually dropping the early section altogether. The late varieties are so much finer in pans for forcing and in the garden, that the wonder is that so many private estates, parks, and cemeteries persist in planting so many early varieties.

* * *

Among small fruits, raspberries are deservedly popular, and some very fine varieties of these have been introduced in late years; the red varieties have the best flavor. For many years Cuthbert was the leader in this section and is still grown very heavily; several other sorts have been planted extensively in recent years and are gradually displacing the one-time leader. Herbert is a favorite with many, although it is lacking in flavor. It is of Canadian origin and is said to have wintered eleven hundred miles north of Boston where minimums of as low as 59° below zero have been recorded, and as many as three hundred nineteen bushels of fruit to an acre have

been picked from it. As raspberries are found in a native state in the Klondyke sections of Alaska, as well as near the great glacier fields, it should be possible to produce raspberries which will stand a very low temperature. Of course, in the more northerly latitudes, the deeper snows make ideal Winter protection.

Minnesota is another very hardy variety which does well in New England and St. Regis which originated on the sandy lands of southern New Jersey has attained considerable popularity; the new canes on this variety fruit freely in the Fall. La France produces a large, handsome berry and gives a heavy Autumn crop; it suckers abundantly and can thus be very rapidly increased. Erskine Park which hails from the Berkshire Hills of Massachusetts is considered by the U. S. Department of Agriculture to be the best of all late red varieties. This by no means exhausts the list of red raspberries. Golden Queen still fills the whole field of the yellow, and Columbian remains supreme among the dark purple varieties.

* * *

Liliums are one of our most important bulbs for forcing. Our importations last year from Japan totaled some seven millions. We also imported some from Bermuda, Holland and France. From the latter country come our candidums which get smaller, poorer, and more costly each year. Some fifteen years ago it was easily possible to get the stalks carrying thirteen to fifteen flowers each; today ten is a high number and a great proportion throw only five to eight. As candidums do remarkably well in some of our southern states, it should be quite possible to produce bulbs equal to or superior to the French; in fact, in southern New Jersey and on Cape Cod, Massachusetts, I believe bulbs can be produced as fine as any we now are importing from France. Years ago Bermuda produced our finest Easter lilies and Harris's grown there were of remarkable quality. Disease and careless sorting of bulbs disgusted growers in America, and for years the Bermuda industry lay under a dark cloud. An expert sent from Great Britain has gradually eliminated disease, and the best lilies I have seen this season in New England came from Bermuda bulbs. If they can give us as good bulbs of *longiflorum giganteum*, we would readily dispense with the large and costly shipments from Japan.

That we can produce good Easter lilies in America is beginning to be recognized. Some of the cleanest I ever grew came from Orlando, Florida. A batch from New Orleans, seen a few days ago, were equal to any which came from Japan, and Texas can also grow good lily bulbs. The increasing cost of bulbs from abroad would appear to open up a new field of profit for some lily propagators here. With the threatened debarment of all bulbs in the near future, lilies included, owing to the terrible dangers from insects and diseases, as yet unknown, which may devastate our forests, fields, and gardens, we may have to submit, if the present autocratic F. H. B. continues to function, so we may as well prepare to produce some lilies here at home as best we can.

UNFOLDING LEAFAGE

Leaves that are unfolding have a charming daintiness in color and plaitings. They exemplify that brave fragility that makes childhood so appealing. A collection of just-opened leaves will make a rare study in design. The willow, a very light, thin, green, tinged with red and woolly-white underneath; birches yellow-green with a warm furry coating of white and fluted like tiny half-opened fans; poplars living green and fragrant with balsam; downy mouse-ear elms, showing every crease and fold made by their swaddling clothes.—*C. S. Monitor.*

The Gourd, the Most Attractive Annual Climbing Vine

DR. E. BADE

OF all the annual climbing vines, the gourds are the most attractive. They are able to cover large surfaces during the Summer, especially when they are placed in a good fertile soil. These quick growing plants which require absolutely no care, should be sown in May. The spot chosen for their growth should be sunny, for

are sown on sunny beds in the month of May. Only the fruit of these plants is beautiful, since, when ripe, they open and show their bright red meat in which the seeds are imbedded. Only at this time are these plants attractive.

But the true gourds are a thing of beauty at all times.

"Nestegg" and flower

Dishcloth (Luffa)

light, heat, and moisture spurs them on to develop in all their luxuriance. Their large beautiful flowers are open from twilight until about 9 o'clock in the morning and are also open on cloudy and cool days. The flowers of the bottle-shaped gourd and of Luffa are snow white, those of the other gourds are yellowish; they are somewhat similar, but much larger, than those of the cucumber.

Two interesting relatives of the gourds are *Ecballium elaterium*, and *Momordia balsamina*. The former is an inhabitant of southern Europe, where it is a common weed. This plant is peculiar in its fruit, which is about

Their quick growth and the profusion of flowers make them doubly attractive. The male flowers make their appearance first. During July the female flowers begin to open and which, after insect fertilization, soon develop into fruit. The profusion and variety of the fruits may be traced back to degenerate forms. Many of their characteristics are, indeed, peculiar. In form they may resemble apples, pears, eggs, melons, oranges, bottles, or clubs, among which the rarer wart-gourd must not be forgotten. The color ranges anywhere from a pure white to a deep orange or from a bright yellow to a dark green.

Dipper (*Lagenaria*)

"Hercules-Club"

as long and as thick as the thumb. It falls from the vine at the touch, and, at the same time, the liquid within, which is kept under high pressure, is squirted out violently, together with the seeds. When cultivated, the seeds should be sown in the open in the month of April.

Momordia balsamina and similar cucumber-like gourds (*M. charantia*) whose leaves are heart-shaped and entire,

The rind may be smooth, fluted, or warty, and have two or more colors so arranged as to give a picturesque effect.

Beautiful ornamental knick-knacks can be made from the fruit with little labor. The gourd, when ripe, has a wood-like rind which is hard and capable of withstanding quite some pressure. First an opening must be made large

(Continued on page 68)

The Calanthe

GEORGE W. MYLES LYDDIARD

THE first hybrid was raised by Mr. Dominy of Veitch's Nursery, between *C. musaca* and *C. furcata* in 1854 and bloomed two years later—this shows us what hybridization will sometimes do, as *C. musaca* is a shy bloomer, whereas the hybrid is a free bloomer.

There are about forty species of *Calanthe*, chiefly natives of Asia and a few being American, both evergreen and deciduous varieties. My remarks will deal chiefly with the deciduous variety and their successful cultivation.

One of the oldest varieties is the *C. Vestita* being introduced about 1848 by Veitch's of Chelsea. This and its sub-varieties has an apple-shaped pseudo bulb and bears a flower stem (when well grown about two inches across) and from one to three feet long—flowers white with yellow throat and blooms about November. There are several named varieties of this type, some of the best being: *Gigantea*—strong grower and usually retains its foliage till the new growth starts and flowers from November to March; *nivalis*—flowers pure white; *porphyrea*—flower spike compact, tinted all over with rose and differing in form from the preceding types; *rubro oculata*—flowers large with crimson instead of yellow blotch in throat and *Turneri*—flowers more compact on the spike and smaller, throat blotched with rosy red.

Personally my prime favorite of all the deciduous *Calanthes* is *Veitchii*, and its various sub-varieties, these can easily be identified by their long bulbs indented in the middle and their large plaited light green leaves. The flower spikes when well grown reach three feet in length and bear an abundance of bloom, which are similar to those of the *Vestita* family but shorter in the lip. They are bright rose color with a white throat and bloom from early Winter till the turn of the year. Three of the best varieties of this type being: *Bella*, very bright pink flowers; *Sandhurstiana* has deep crimson flowers, and *Sedenii* which has deep rose colored flowers, darker altogether than *Veitchii*.

The preceding varieties I have especially mentioned as they are old, true and reliable. There has been of late years quite a number of very pretty and useful novelties introduced, a number of which I have not had the opportunity of handling. The following, however, I can vouch for: *Baron Schroeder* variety; *albescens*, one of the strongest growers; *Byran*, *Chapmanii* (*Ruby* × *Veitchii*), 1906; *Harrisii*, flowers white, flushed pink; *Mrs. C. Vanderbilt*, *Darblyana* (*Regnieri* × *Vestita*); *C. Ruby* (*Sedenie* × *Vestita*); *W. Murray*, *Victoria Regina* (*Rosea* × *Veitchii*).

All the deciduous varieties of *Calanthes* require the same treatment. This is the usual course of cultivation I follow, and I have been successful in growing some quite good and useful patches of this most useful class of Winter flowering orchids: As soon as the plants have finished blooming, I separate the new bulb from the old, placing the former into four-inch pots with coarse sand only, which is kept just moist in a temperature of about 60° to induce a steady and robust growth or growths. As soon as the new growths are about four inches long they are potted into five- and six-inch pots, according to the size and strength of the bulbs, and placed in strong heat and never allowed to go back. They are given as soon as potted one thorough watering to settle the potting compost thoroughly round each bulb. The smallest bulbs are potted into eight- and ten-inch pans, five to six in each, care being taken to plant all the bulbs in the center of the

pan with the growths outward to insure the plants as much freedom as possible to develop their new bulbs. These pans will be found, when in flower, very useful indeed from a decorative point of view. The plants at this stage require more than ordinary attention for a few weeks till they establish themselves. Great discretion should be used in the matter of watering and ventilation as the grower must bear in mind that they thrive best in strong heat and an abundance of atmospheric moisture at all times, till they have finished their growth towards the end of September.

These plants love light, but will not stand the direct rays of the Summer sun. Give a light shading to protect them during bright weather, but on no account use a heavy or permanent shading, as very often this is how plants are spoiled and their foliage badly rusted; also never crowd your plants. If you have space to grow a dozen plants well, do so but don't try to grow two dozen and spoil the whole batch. How often one sees this sort of thing, even in some well appointed gardens, trying to grow more than there is really space for, and getting some very ordinary results.

I always endeavor to keep my plants as near the glass as possible without touching it, and allow them plenty of room for light and air to get around the plants.

About July when the bulbs begin to swell is the time to start to feed them. Being terrestrial plants they require quite a lot of careful feeding to help bring them to perfection, and experience has taught me that *Calanthes* love a change of feeding from time to time. I usually start feeding with manure water from cowdung and soot in a weak state about twice a week, gradually using it stronger as the bulbs develop, as you would for mums. I vary it to some standard chemical manure, such as Clay's, Thompson's, etc.

When September arrives some of the varieties show signs of finishing their season's growth by their baby leaves changing color. Water in both liquid and atmospheric form should be gradually diminished as time goes on, but on no account must all moisture be withheld till the plants have finished growing.

I have often seen quite good batches of plants ruined by the grower drying the plants off too suddenly. This is as detrimental to them as over watching them at this stage. As soon as the flowers begin to open the plants should be moved into a dryer house with a night temperature of about 60°. By doing this your flowers will gain substance and color and last in bloom much longer.

The compost I use is three parts good turfy loam, one part peat, both hand picked and sifted to reduce the soil from the loam in a quarter-inch sieve, and one part well rotted cow manure rubbed through one half-inch sieve. See that manure is not too wet or on the other hand too dry, for if it is, it means hard work to get through sieve and does not mix so evenly with the loam and peat. Mix thoroughly and to each two bushels add a four-inch pot of soot, one six-inch pot of charcoal broken to the size of peas, and one four-inch pot of bone meal with a liberal sprinkling of sand (coarse, not fine).

The bulbs should be potted barely an inch deep in the compost, making it fairly and evenly firm, not hard on any account. Great care should be taken not to make the compost too firm on the side of the bulb from which comes the growth and the tender fleshy roots.

(Continued on page 68)

What the Home Garden Should Be

THOMAS W. HEAD

WERE I talking to each one individually my first question would be, "What kind of a garden have you?" I am sure that each could tell me something in reply that would interest and instruct. It is not alone the extent under cultivation that measures the attractiveness and value of one's garden. No matter how small it may be if it is well done, tidy and fertile, above all showing a well defined purpose and well carried out. A garden without individuality misses much of its charm. Why should there not be as many types of gardening as there are types of people? Nature never repeats herself, and he is a poor gardener indeed who is unable to give distinctive character to the domain under his care, whether it is his own little dooryard plot or a vast estate of many acres. He who aims at nothing better than simply to lay out his home grounds in whatever may be the prevailing style, selecting his material and its arrangement with no higher motive than to imitate what some one else has done, is surely entitled to our pity.

Lord Bacon once said, "A man shall ever see that when ages grow into civilization and elegance, men come to build stately sooner than to garden finely." So we find in this country of ours, in these communities longest settled, the greatest advance made in gardening art and the people more ready to divert their attention from commercial engrossment to a consideration of beautifying their home environments. We see the people more readily inclined than some in the younger sections of our country, to forsake the crude and grotesque plantings of imitations of animals, birds and so forth and substitute the more natural, rational and artistic arrangement and more pleasing variety in the adornment of our parks and residential grounds. There were a few who were carried away with the ribbon bed craze, for a time, but we learn by our mistakes and I think we can safely promise, with hand uplifted, that we will never commit that offense again.

But let us watch out that we do not allow ourselves to go to as absurd lengths in other directions. There is a suggestion of sameness in many of the shrubbery plantings now becoming so popular that it is as tiresome and meaningless as it is unnecessary with the almost endless variety of material at our disposal. If we are to make positive progress in our gardening and not simply revolve in cycles we must avoid crazes and fads. Our resources are boundless and no single style of gardening can lay claim to unquestioned superiority under any and all considerations. Individuality is a possibility and should be striven for. We have all seen streets where the houses were identical in every respect, one with the other, size, architecture, color, surroundings, so that it would seem that an occupant must needs look carefully at the door number before venturing into his home.

The ready-made effect leaves an unfavorable impression and the monotony wearies us. By all means let us do all we can to prevent such a condition in our garden scenery. Tiresome repetition is as much to be deplored in belts of dogwood, hydrangeas and berberis, as it was in the now discarded gardening of 25 years ago when everybody felt obliged to mutilate the green lawn with a scroll of red coleus or geraniums edged with dusty miller or such.

As to the laying out of a garden, as before remarked, I believe in individuality, but governed of course by correct artistic perception, something which we all have in greater or less degree, and which by observation and experiment we may cultivate to a high plane, and so by a general knowledge of the requirements and possibilities

of plants, shrubs and trees at our disposal. I would call attention to a few other features that seem indispensable in the arrangement of an enjoyable home garden. First, I want some seclusion, either actual or suggested. I object to being one of a number of residents in a continuous park. I would not be understood to advocate returning to the old style of fence division, each bit of fence of a different model, height and color from its neighbor, but when park-like effect in the aspect of our suburban homes is secured at the expense of the home idea, it costs too much. It is possible to indicate the spot where our garden ends and our neighbor's garden begins, to mark the division between our domestic Eden and the public road and to ensure a welcome privacy, without necessarily interposing a high hedge or a forbidding stone wall. Tidiness, you will all agree, is an indispensable requisite in the home grounds. To maintain this in its fullest sense, there is plenty to be done besides keeping the lawn close clipped, the weeds dug out and the litter picked up. The memory of the old decrepit lilacs, honeysuckles and Rose of Sharon in some of the ancient gardens when I was a boy still haunt me and I can see the greatest menace to the popularity of the flowering shrubs in the future in a repetition of this neglect which was so largely responsible for their temporary banishment from public favor. However picturesque an old gnarled oak or cedar may be, a gnarled lilac has no claim on my admiration. Constant attention is the price we must pay for an attractive, healthy shrubbery plantation. Where trees or shrubs have grown so that they are about to interfere with their best development, thin them out at once before the harm is done, taking away the least desirable. When a specimen shows indication of infirmity, throw it out and substitute a youthful one. To do this requires courage. We will learn after a few such experiences to sympathize with and pity the man in charge of public grounds, who, in the proper carrying out of the duties for which he is paid, has to face unreasoning and spiteful criticism on all sides from people who go frantic over the unavoidable trimming and thinning out of half suffocated saplings in an overgrown wilderness but yet look on with indifference or even approval when a noble elm that has seen the centuries come and go is ruthlessly destroyed to make way for a trolley line.

Our subject is an endless one. The need of wise discretion in the intermingling of native and foreign subjects, the uses of evergreens, of climbing plants on the house, of hardy perennials, of bedding plants, and annuals in association with shrubbery borders, the securing of a steady succession of bloom when selecting material, the maintaining of a proper equilibrium between wildness and artificiality, questions of color, composition, sun and shade and the obligations which civilization imposes upon us to see that our gardens and fields are not breeding places for noxious weeds, insects, pests, these and an infinity of other things suggest themselves to one when he begins to think about his garden work, but space will not permit me to dwell on them further.

The garden is our most natural abode. We are told that our first parents had a garden for their home but that their first sin caused their expulsion from the beautiful place. What a tribute, this, from the Almighty to the garden. Is it strange that ever since, when man has sought to find perfect happiness, he has surrounded himself with gardens, or that flowers and gardens have been a

(Continued on page 68)

Disappearing Species

WILLARD N. CLUTE

HOWEVER much eminent lecturers and Southern politicians may disagree with the evolutionists as to how the plants and animals came upon the earth, they are not likely to differ much over the statement that many species are gradually disappearing. The evidence is all too conclusive. In very recent times we have seen the passenger pigeon, and the quagga, the sea-cow, great auk, exterminated and the buffalo, whale, prairie-hen and many kinds of birds brought to the verge of extinction. That a large number of others are also on the way out can scarcely be doubted. As regards the cases mentioned, it may be objected that these are not due to natural causes but are mainly due to the activities of man. Granting this, the proposition is still the reaction of one species upon another. The results in the end are the same, whether the struggle is between plant and animal, between plant and plant, or between the animals and that most destructive animal of them all—man.

It is likely that a thousand small adjustments are constantly taking place in fitting plants and animals more exactly to their surroundings. It is only when the adjustments are too slow to preserve the life of the species, or when they are more rapid than usual, that we notice them. In the case of the passenger pigeon, extermination was unusually rapid. It occurred in the span of a single lifetime. The death of the chestnut trees has been still more rapid. Twenty years ago, our eastern mountains contained numerous magnificent forests of chestnut. Now the tree is practically extinct; killed by a microscopic enemy in spite of the best efforts of man to protect it.

The fossil record is chiefly a record of species that no longer inhabit the earth; of unsuccessful species that failed to keep up with the changes in their surroundings. The plants that formed the coal measures are not represented on the earth today. Indeed, the existence of fossil palms in Greenland and the occurrence of coal beds in regions now covered with snow and ice show very conclusively that great changes must have taken place since the coal plants flourished. In other regions we may find species that have not entirely disappeared, but whose restricted ranges show how greatly their race has declined. The magnolias of our Southern States and Eastern Asia were once common in Europe as shown by their fossil remains, but they do not grow there now. The redwoods now found only along our Pacific Slope were once spread entirely around the earth in the north temperate zone.

When we ask what brought these species low there is no definite answer. Perhaps it was a change in climate, perhaps too great a difference in temperature, or moisture, or some other condition of which we are ignorant at present.

Probably few of us realize how very dependent even man himself is on the conditions of his environment. Any one of a dozen slight changes that might take place in the earth's atmosphere would instantly wipe him out of existence. A succession of years too cold for the growing of food crops would force him toward the equator just as an increase of warmth would induce him to move nearer the poles. The remains of once populous cities in the deserts of Asia and the abandoned cliff-ruins so widely scattered in our arid Southwest point mutely to the fact that moisture con-

ditions on the earth have changed greatly since man made his appearance. That he could not stand against some of these changes is shown by the successive waves of migration that have flowed into Europe from the south-east, driven out by the increasing dessication of the region.

What man has done to exterminate various species is not worth mentioning in comparison with Nature's efforts in the same line. The broad sea that once rolled from the Gulf of Mexico to the Arctic ocean contained many species that disappeared with its subsidence. At the same time a vast region was thrown open to such land animals and plants as could migrate into it and alter their requirements sufficiently to retain their place in it. Changes of similar kind have happened again and again over the earth; indeed, they have not yet ceased to happen. When the changes have been small, or have taken place very gradually, plants and animals have probably changed fast enough to keep pace with them. But when the changes have happened to be rapid, many species have doubtless gone down to defeat, unable to maintain life in a greatly changed environment.

Nor is the life of a species entirely bound up with its inorganic or physical environment. Often the dependence of one species on another, or their mutual reactions may result in the decline and death of one or both. A plant species may disappear for want of the proper pollinating insect, or because of the presence of some leaf-eating insect or other animal. Or it may, as in the case of the chestnut, be attacked by some disease that it is unable to survive. Still further, the absence of the pollinating insect may be due to the destruction of some very different plant upon which the larval insects feed and this in turn may be due to the drying up of some distant swamp, or the flooding of some valley in which the plant grew. Plants that are incapable of self-pollination may have their very existence threatened in this way.

Of all the agencies that threaten the existence of plants and animals today, man seems to be the most important. By lumbering, burning, draining, flooding, filling, excavating and cultivating he has greatly changed the face of Nature and rendered many localities entirely unfitted to support the species that formerly inhabited them. But these very changes have made new and fertile fields for still other species that could not get a foothold so long as the original tenants were not disturbed. Moreover, the cultivated crops that man prizes often harbor insects or diseases that spread to the wild forms, while occasionally the tables are turned and the wild things provide diseases that inflict great mortality on the cultivated crops. As a matter of fact, some innocent appearing plant may harbor an organism very destructive to a very different species.

The total result of these interactions of species with species and of species with climate and the changes in the surface of the earth must be a series of changes in form and structure which preserves the successful forms from extinction. Thus have the plants been modified to fit their environment. Thus have resulted new forms which in time may have become distinct species. To doubt it is to doubt the evidence of our senses. And this is evolution.

Armeria—Lychnis

RICHARD ROTHE

ARMERIA, a genus of the order Plumbagineæ, commonly called Sea-pink or Thrift, consists of a number of useful rock garden inmates of long standing. The nomenclature of species in standard works is in a chaotic state and as many of the species merely differ under the microscope of the botanist our interest is best limited to the few distinct forms we are familiar with.

Armeria maritima splendens

Armeria cephalotes, valuable on account of its late flowering, may be found listed as *A. formosa*, *latifolia*, *mauretanica* and *pseudo-armeria*. The round headed blossoms of the true *cephalotes* appear in early Autumn and are of a deep rosy crimson. The species *Armeria plantaginea*, going also under the names *leucantha* and *scorzoneræfolia*, is at its best during June and July. Its blossoms are rosy red and those of the variety *alba* are white.

Best known to most of us is the common *Armeria vulgaris*, growing wild along the coast lines of Great Britain and also abounding on rather dry open sunny plains of Central Europe. Its synonyms are *A. elongata maritima* and *Staticè Armeria*. The garden forms of it listed in American catalogues under *Armeria maritima splendens*, *splendens alba* and *Laucheana*, remain the most desirable for American rockeries. The flower heads of *maritima splendens*, the subject of our illustration, appear in rosy pink or in white, while those of *Laucheana* are of a bright pink color. Their very resistant tufted foliage covering the ground densely and their decidedly handsome blossoms borne on thin wiry stems make the cultivated thrifts an ideal material for filling the pockets of the sunny locations of rockeries and dry walls. They also prove effective when employed for edging of borders in herbaceous gardens.

Armerias may be raised from seed sown in cold storage early in Spring or propagated by divisions. Seedlings flower the second year. Plantations should be made in light sandy soil rich in humus. Do not forget a light leaf covering for Winter protection.

LYCHNIS

The name *Lychnis*, derived from the Greek *Lychnos*, the lamp, refers to one of the chief characteristics of this hardy plant genus; that is, the strong fiery red of the flowers of its foremost species. Indeed the intensity of the red of *Lychnis chalcedonica*, *L. fulgens* and *L. Haageana* is rarely eclipsed by any other garden flower. The prevailing tendency among many garden owners to keep red out of their color schemes is no doubt in part the reason for their frequent omission in modern gardens.

Few perennials can be as easily raised and propagated as *lychnis*. Early Spring seedlings flower profusely the first season. All species are extraordinarily hardy, requiring only a minimum of care.

Lychnis at present remains the perennial of the beginner with a small purse undisturbed yet by color riots. It is the perennial of rural housewives and it claims its undisputable space in every old-fashioned garden worthy of the name. But as soon as we take up the cultivation of the white-flowering varieties such as *L. chalcedonica alba plena*, *L. vespertina*, *L. flos-cuculi alba plena* and above all *L. viscaria alba grandiflora plena* then we begin

Lychnis viscaria splendens

to realize the existence of beautiful forms well worth their space in modern gardens. The flowers of the last variety mentioned represent a fine material for filling vases. Color harmony supreme or of little concern, I believe we cannot afford to omit the *Lychnis*. The rich and glowing magenta red of *L. viscaria splendens fl. pl.* may be an impossibility in many modern color schemes, nevertheless its dazzling strength will always appeal to us so forcefully that we can never lose sight of it. At present the rock-garden offers the best opportunity to use it to full advantage. Within its precincts we may also enjoy the low dense cushion-like growth of *Lychnis alpina*, covered with legions of little rosy-red blossoms and the two less known species *L. pyrenaica* and *L. yunanensis*.

My impression is that the genus *Lychnis* of late has been somewhat neglected. In taking up the cultivation of the best species and varieties we are apt to increase our cash returns and, in availing ourselves of the opportunities for effective garden use, we doubtless will add to the beauty of our home grounds. I particularly wish to call attention to the quick and easy raising of the single-flowering species from seed.

Kind hearts are the gardens,
Kind thoughts are the roots,
Kind words are the blossoms,
Kind deeds are the fruits.

Do not look for wrong and evil,
You will find them if you do;
As you measure for your neighbor,
He will measure back to you.—Alice Cary.

Rambling Talks on Plants

FLORUM AMATOR

EPIGÆA REPENS, Trailing Arbutus, is by no means our earliest Spring flower, but it is one of the sweetest and prettiest. The flowers of *Symlocarpus foetidus*, the Skunk Cabbage, appears weeks before those of the Trailing Arbutus are seen; so do the tiny, white flowers of *Draba verna*, Whitlow grass; the hill-side type of *Viola palmata*, variety *cucullata*, and the composite flowers of *Antennaria plantaginifolia* also above their silky-woolly leaves. It is, however, when the Trailing Arbutus, the dainty Anemones, the fuzzy-leaved Hepaticas, Liver-worts, and the pearly flowered Sanguineas, Bloodroot, are in bloom that we feel Spring is surely here again.

Some people object to the botanical use of names, and affirm that English names are good enough, but just note two facts bearing on this discussion; firstly, you may safely use the words *Epigæa repens* in talking or writing to a man of any nationality. He will understand what plant you mean, for the scientific botanical name of the plant is the same in all languages, but the name, trailing arbutus will be understood only by those who speak English. Secondly, the name *Arbutus* conveys to us no characteristic of the plant, but *Epigæa*, from the Greek *Epi*, upon and *Ge*, the earth, exactly describes the plant. It grows not upright but upon the earth; *Repens*, a Latin word, is well translated by our English word trailing, but as previously mentioned, all nationalities understand *repens*, but not trailing.

Not unfrequently those who go out in early Spring to search for Trailing Arbutus blooms, report on their return that it is in bud. They could have truthfully made the same report in the previous December, for this plant forms its flower buds in the Autumn of the previous year, and they remain green and dormant till the next Spring. If gathered in the early Spring and placed in water, these buds rarely develop into flowers. But they will expand, if placed either in a Wardian case or in a tin botanical case or tin box partly filled with moss. The stems of the arbutus should be stuck into the moss; the covers placed on the case or box, and the case put into a rather warm room. The blooms brought out in this way will be large, but will lack to a great extent the pink tint which they have when they flower in their native habitat.

Of all our native flowering shrubs, none are more attractive by reason of the color, form, and fragrance of their flowers than the Azaleas which through their profusion of blooms make our woodlands gay in Spring. In our northern woods, *Azalea nudiflora* blooms in May. The flowers of this species, which are pink, show a considerable range of shade in that color from extremely light to quite dark. It prefers a somewhat dry location in a rather open woodland. In its native habitat, *Azalea nudiflora* makes a rather irregular growth and attains a height of four to six feet. When transplanted into the shrubbery, and kept closely cut back for a year or more, after being moved, it makes a bushy growth and on this lower growth flowers freely. In our somewhat moist and even in our swampy woodlands in the north, we have another Azalea, which blooms in July. The specific name of this is *viscosa*, so named because its white flowers are quite viscid or sticky. This sweet scented Azalea, found often on the margins of swamps along with *Magnolia glauca* and *Clethra alnifolia*, will thrive in a shrubbery

which is not heavily shaded, and in a somewhat dry location. Its adjustment to the change from a heavily to an only partially shaded and from a wet to a rather dry location, as has been observed, is not a characteristic of the *Azalea viscosa* only, but belongs to other plants as well; for example, to the beautiful pink flowered *Hibiscus moscheutos*, which can be removed from its natural surroundings in a wet marsh to a rich upland position and will thrive there. As a rule, however, it is much better in transplanting native plants into cultivated shrubberies, to give them as nearly as possible a location similar to their native habitat.

In Pennsylvania along the water courses in the moist woods, the *Azalea arborescens* grows. This species blooms in May; its flowers are rose color, large and sweet scented like those of *viscosa*, but not sticky; they appear before the leaves.

In the mountainous regions from Ohio to Georgia, but especially in North Carolina, grows *Azalea calendulacea*, the flame colored azalea, or Flaming Pinxter, in masses covering an acre or more. The normal color of this flower is yellowish crimson, but it varies from a light to a deep yellow and sometimes to red. The effect of masses of this azalea, which grows six to eight feet high, is extremely brilliant. Still another southern azalea is *Vaseyi*, whose blooms are of a delicate pink color, and contrast strikingly with the bold flame or orange colored flowers of *calendulacea*.

In April, in the North, appear only a little above the surface of the ground between a pair of large velvety, dark green leaves, which overtop them about six inches, the purplish flowers of *Asarum canadense*. The common name of this perennial herbaceous plant is Indian Ginger; it is also called Canadian Snake Root. Its rhizomes by which it multiplies rapidly, have a medicinal value. From Canada to Virginia, over a wide range of territory, it grows wild in rocky, half-shaded situations. In cultivation it is quite useful in rockeries both on account of its soft green leaves and its odd shaped flowers.

In Virginia and southward there are two other species of *Asarum*, namely, *virginicum* and *arifolium*, but they are much like *canadense*, except that their flowers appear in March. In California there is still another species called *caudatum*, having brownish-red flowers, which are not so much concealed by their foliage as those of the other species. If you have a bare space, even if rather rocky, which you would like to cover quickly with a mass of low, soft, bright green foliage, you can depend upon one of the several species of *Asarum*, suitable to your latitude, to do this.

Ever since many years ago, in the last of May, we found *Actæa alba*, Baneberry, growing near the edge of some ledges on a partly shaded hillside, we have regarded it as an interesting plant. Its attractiveness lies not so much in its racemes of whitish flowers, as in its general appearance brought about by the ternately compound leaves with which its upright stem about two feet high is clothed, and its pretty white berries which follow its flowers. This *Actæa* is an excellent plant for naturalizing in shady woods or planting in a general collection of herbaceous perennials. Another species of *Actæa*, differing very little from *alba* in general characteristics and having the same kind of flowers, is *spicata*, which has red berries. Some botanists consider *alba* only a variety of *spicata*.

Some Good American Shrubs

H. E. DOWNER

IN various ways considerable attention is being directed towards a better appreciation of native plants, both in their native haunts and also with reference to the suitability of many of them for garden planting. A long list could be prepared of the trees, shrubs, and herbs of our roadsides, fields and woods, from which the materials for very pleasing compositions could be selected. These notes, however, are written for the purpose of bringing to notice some of the native shrubs of outstanding value, at the commencement of another planting season. Some landscape designers have made good use of them in large plantings, but most of those who sell and plant shrubs seem to be better acquainted with some of the more showy of the exotics and garden varieties. True enough, we do not wish to be deprived of the plants from foreign parts, as witness the furore caused by Quarantine No. 37. We can find room for all that are desirable. But the real art of planting is in the proper placement of plants which fit the surroundings, and this is something not always achieved, even though the choicest material may have been used. From the following indigenous species a selection can be made suitable for planting in practically any situation.

Rhus canadensis, a fragrant Sumach. This is a very distinct looking sumach, being a dwarf spreading bush, so that it fits nicely in the front of a large planting and is first class to use on a rough bank. From tiny, gray, catkin-like spikes developed in the Autumn, greenish yellow flowers open with the leaves of Spring, followed a few weeks later by attractive red fruit. The leaves are tri-foliolate and contribute red and yellow shades in the display of Autumn color.

Dirca palustris or Leatherwood. A small shrub of shapely habit, taking on a compact rounded form when grown in the open, very attractive in the first days of Spring when the small yellow flowers of tubular form open in advance of the leaves. The branches are pliant but almost as tough as hempen rope.

Xanthorrhiza apiifolia or Yellow Root. Here we have a very fine shrub for under planting or to use as an "edger" for planting of larger shrubs. Although it is found along the shady banks of streams, it thrives in quite dry soil, but does grow best in partial shade. In height it does not appear to exceed three feet, and its habit of suckering freely is a good one. It flowers profusely but unobtrusively, the slender racemes of small, star-shaped, chocolate colored flowers preceding the development of the celery-like leaves, which take on a glow of gold in the Autumn.

Benzoin æstivale or Spice Bush. A clean-growing large bush, fine for a background and doing well in moist wooded places. The branches are thickly studded with clusters of tiny yellow flowers, without petals and almost stemless but making a cheery glow that is most welcome in the days when Spring and Winter seem to be contending for mastery. The foliage is good all through the season and finishes up a bright yellow. The fruit is bright scarlet, much loved by the birds.

Hypericum prolificum. A shrubby St. John's Wort, which under cultivation makes a dense bush about five feet high. In flowering, it is all that the specific name implies. The flowers, having bright yellow petals and a mass of yellow stamens make a great showing in mid-Summer, when there are few rivals to attract attention in the shrubbery. It is quite happy in light soil.

H. aureum. This species is not as tall as the former, is of very good habit and has larger flowers. A fine shrub for Summer blooming. Although a native of the South, I have seen it thriving very well in Massachusetts.

Clethra alnifolia or Sweet Pepper Bush. A valuable shrub, generally found inhabiting swampy ground but will grow very well in good garden soil and will stand shade. The fragrant white flower spikes are produced in August, when blooming shrubs are rare.

Baccharis halimifolia or Groundsel Shrub. This is a plant with the unusual distinction of being a shrubby member of the great composite family. It is found along the eastern coast and is therefore well adapted for planting in seaside gardens. I have seen it growing well in good garden soil, but how it would thrive in dry sandy soil I do not know. The flowers are inconspicuous and are staminate or pistillate borne on separate plants. The abundant white silky pappus of the female plant presents the appearance of a shrub in full bloom in late September and October. It responds well to the same pruning treatment as given the Japanese Hydrangeas.

Euonymus americanus or Strawberry Bush. This is a shrub of slender habit, most effective when several plants are grouped, and in a mixed border the bright green stems show to advantage. Its glory lies in the display of fruit, and when the warty capsules of rosy red burst open and show the bright scarlet seeds the effect is gorgeous.

Rubus odoratus or Purple Flowering Raspberry. A vigorous, upright grower, increasing from the roots to form a spreading clump, a good plant to fill a shady corner. The leaves are unusually large for a *Rubus* and the flowers, nearly two inches across, are produced almost all Summer. The fruit is palatable though not to be compared with cultivated raspberries.

Sambucus canadensis or Common Elder. If this roadside shrub could be regarded as a rare exotic, it would undoubtedly be in good demand for garden planting. A good mass planting is most effective in June, when the large flat clusters of white flowers are open. The resulting display of purple berries seldom lasts long, as those that are missed by the gatherers for wine-making are swallowed by the birds.

Ilex verticillata or Black Alder. A deciduous holly whose berried branches used in Christmas decoration are familiar to more people than the growing plant. Found chiefly in swampy places, it does not insist on a wet soil in order to thrive. Individual plants do not make heavy specimens so that a planting is more effective when several plants are grouped.

Aronia arbutifolia or Red Choke-berry. A good ornamental shrub for a mixed planting, and in need of good soil, with plenty of moisture to be at its best. The habit of growth is bushy, the flowers are white, in clusters like its relative the Hawthorn, and followed by bright red berries.

Cephalanthus occidentalis or Button-ball Shrub. Another swamp inhabitant that well deserves a place nearer the habitations of men. When well suited, it makes a big spreading bush eight or ten feet high, and as far across. It is very attractive in July, when the white globular flower heads, each composed of a great number of small tubular, fragrant florets, are at their best.

Vaccinium corymbosum or High-bush Blueberry. In moist soil, this well-known berry producer is a very satisfactory shrub to cultivate, not so much for the edible

fruit as for the gorgeous display of colored foliage in October. When well suited, it grows into a good sized compact shrub, good looking all through the season.

Cornus paniculata or panicked Dogwood. This is a very useful shrub for mass planting, of medium growth and very bushy. It makes a very attractive showing in Spring with its numerous clusters of white flowers, and again in early Autumn with the white berries, which are carried on red stems. Its branches are smooth and gray, so that it is a particularly good looking shrub the year round.

Viburnum cassinoides or Withe-rod. This is perhaps the best of the native viburnums for garden purposes. It is excellent for massing in partially shaded places, under such conditions the growth being somewhat loose. In the open, it makes a compact well-formed bush about six feet high. The flat cymes of creamy white flowers are usually borne in great profusion, but its glory is the ultimate display of fruit which in early Autumn changes from green to bright rose, then to blue black, the transition of colors producing a marvellous effect.

V. opulus or High-bush Cranberry, is a very handsome species in flower and fruit. The white flower clusters have an outer ring of larger, more showy sterile flowers. Its clusters of large brilliant red berries are especially showy and hang on all Winter, the birds seemingly not caring for them.

V. dentatum or Arrow-wood is a slender grower up to ten feet or more. It has good looking foliage and will stand shade. The small heads of cream colored flowers open around the first of June, the resulting berries turn blue black by early Autumn, and are usually cleaned up early by the birds.

V. acerifolium or Maple-leaved Arrow-wood is a sturdy dwarf which does well in dry shady places and is well placed along the edge of a plantation. It is particularly attractive in the Autumn when the leaves assume rich tints and the clusters of fruit change from red to dark purple.

WHAT THE HOME GARDEN SHOULD BE

(Continued from page 63)

fruitful theme for painters and poets? A home without a garden is not quite a home. A child whose first impressions of the world in which he is destined to live and work are associated with flowers and trees and all that goes with them of pure air, birds and sky, and health, physical, mental and moral, begins his career with a tremendous advantage; no teachings are purer, no education more effective, in laying the foundation of future character than familiarity with these, the best gifts of the Creator to mankind, and he who cultivates a plant for love of it cultivates his own mind and heart at the same time.

THE GOURD

(Continued from page 61)

enough to permit a teaspoon to enter freely. Then remove the seeds and the soft spongy meat and scrape off as much as possible of the harder meat. When all parts of the shell have been perfectly cleaned, the gourd must be dried.

This can be conveniently and satisfactorily performed in some warm room, although they may be placed with equal success in the warm sun. The intense heat of a stove should be avoided since the fresh gourds are apt to shrivel when dried too quickly. When dried the gourds retain their shape and are not easily broken.

The natives of the tropics and subtropics, where these plants are found, protect and cultivate these vines to some

extent. For, in the first place, these plants give them the material for saucers and bowls, ladles and water bottles. A material fashioned by Mother Nature into all possible shapes and forms, and which, with but little work is ready to be used as household articles. The natives, whose notion of artistic instinct is more or less vague, adorn these articles in various ways, just as their sense of beauty may dictate. Almost all their gourds show a few parallel decorative lines, while others are adorned with more elaborate designs.

THE CALANTHE

(Continued from page 62)

Calanthes can be propagated to increase one's stock, if desired, by cutting the bulbs transversely and standing them in pans of sand (coarse) which should be placed in strong heat in the propagating frame and kept moist. By this method you will get small but healthy bulbs to increase your stock for the following year. Another method being to pot up some of the strongest of your old bulbs (two years old) which will with ordinary care throw you some quite strong young bulbs for you to work up for the next season. To insure success by this method, carefully examine under the base of the bulb for a dormant eye or lead, as this is usually where they are found, whereas with a one year old bulb, the growth or lead comes from the side of the bulb base.

Calanthes are often infested with white and brown scale. These, of course, must be gotten rid of by careful sponging, the leaves being very brittle and easily damaged. The worst disease the grower has to contend with is the black-rot or spot, a fungi pest which is fatal to the *Calanthe*. Take my advice, if you ever have the misfortune to get this in your plants, the quickest and best way is to burn the whole lot and get a new stock—as it spreads year after year from the same stock. The disease is often caused by over watering coupled with low night temperature.

The late B. S. Williams of Paradise Nurseries, London, in one of his works on Orchids quotes an instance of seeing a plant of *C. Veitchii* in the collection of S. Mendel, Esq., grown by Mr. Petch, with bulbs almost eighteen inches long which threw a spike six feet high and carried over one hundred and fifty blooms. (*Veitchii* is *Limatodes Rosea* × *Calanthe Vestita* by Dommy.)

The *Calanthe* is one of the easiest of orchids to hybridize after a little experience, and they have a great advantage over most other orchidaceous plants in this respect, as the seed ripens in three or four months from the time of fertilization, and it takes from two to three years from seed-sowing to their flowering stage. Some difference to most *Cattleyas*, *Laelias* and *Brasso*, etc., which take anywhere from six to ten years from seed-sowing. The seed should be sown on the compost previously recommended for potting purposes, and be kept close in a temperature of 80° to 85° till the seedlings appear. These want very careful handling indeed when very young, but when once established are easily managed as long as one has a good steady heat of 70-75° by night with an additional rise of about 10° during the day. I have used the following chemical formula for *Calanthes* twice a week during their strong growing season with excellent results:

4 ounces of Potassium Nitrate Saltpetre

4 ounces of Ammonium Phosphate

Dissolve in four gallons of soft water and use two ounces to each gallon of water

Our deeds determine us as much as we determine our deeds.—*George Eliot*.

In the Garden and in the Greenhouse

GEORGE F. STEWART

IN THE GARDEN

WE have now arrived at the season of the year when everything is waking up from the long Winter rest of the past months. In late March and early April the gardener has to keep alert that nothing is forgotten in the way of preparation for the coming season. His head, and many times his hands also, has to be in good working shape. Many small important things are likely to be forgotten that later on might hamper him in his work. Daily reference should be made to notes on the previous season's work. I have also found it of great benefit to all concerned to take my helpers into confidence in planning the work for the coming season. Draw to their attention that we are working jointly for the same employer; that he is entitled to all the brain power we possess, and should they notice anything that I may overlook, not to hesitate a minute to remind me of the same, and I will thank them for it. I am a great believer in encouraging independent thinking, and I heartily agree with a very able financier I once worked for, who said that he had obtained some very fine ideas from men that were considered fools.

I have no patience with the type of gardener I heard of lately, who told one of his helpers that he was not supposed to think; he was here to do as he was told. We have had experience with such in bygone days. I knew of one some years ago who told an assistant to go and water a certain bench of planted out plants. The man went and after looking it over, and examining the soil, came back and reported that he did not think it required water. He was ordered back to water it immediately. The gardener made the poor fellow water the bench every day for a week. Such treatment I call tyranny. One can readily imagine the conditions of that poor bench of plants.

As a rule at this season, from March 15 on, snow is pretty well gone, and if perchance we have late storms it does not last long. Snowdrops and other early Spring bulbs will be beginning to flower, reminding one that Nature is beginning to put on its Spring glory.

The lawns will now need attention raking up all twigs and leaves that may have fallen on them during the Winter. Bare patches will have to be seeded and any unsightly depressions filled in by removing the turf and filling it with loam. A good topdressing will also be in order. I prefer bonemeal and wood ashes, also an application of lime. I don't like barnyard manure as it is almost sure to bring in many seeds of dandelion and other pernicious weeds that disfigure so many lawns. Of course, if no limit is set on help, a lawn can be weeded regularly, as well as any cultivated piece of ground, and the so-called natural manures lend a deep lustre to grass and are more lasting in their effect than the artificial fertilizers. After the lawns are cleaned and topdressed, it is better before mowing commences, to give them a rolling with a good heavy roller. It gives a nice level surface, and any small stones that may be lying loose on the surface are pressed into the ground out of the way of the knives of the lawn mower. Be liberal with lawn grass seed, as if one has a good thick seeded lawn, it helps to crowd out weeds.

As soon as frost is out of the ground and the soil in fairly good condition get all digging and ploughing pushed forward. If it was done in the Fall it will not be sufficient, as the Winter has baked it down quite hard, and soil always delights in a good stirring up. Dig deeply, and if time and labor are available, trench the ground.

In ploughing in my young days market gardeners made use of a subsoiler in the furrow after the plough, loosening up the subsoil. The result was that the ground was worked more than twice the depth of ordinary deep ploughing. This extra amount of labor was always apparent in the extra heavy yield at harvesting time. A missionary told me some time ago, that the Chinamen are masterhands at deep cultivation of the soil. Where he was located they had very small farms and manure was not over plentiful, but they made up for the lack of it by deep cultivation with very crude tools. The whole family worked and turned it over year after year to a great depth. The result was a quantity of crops that would astonish a westerner. He was brought up on a farm, therefore knew something about production.

One of the first and best outdoor vegetables, of course, is asparagus, and the bed should receive early attention. To grow asparagus well it requires plenty of plant food. In fact, it may be considered a gross feeder. Dig in plenty of barnyard manure as soon as the soil can be worked. It also likes the soil kept open, which necessitates frequent cultivation. When the ground is stirred, applications of tankage or any killing house refuse may be given. Sait, superphosphate and soft coal soot is also recommended by good growers, giving a little every time the ground is stirred up. In making a new plantation, secure strong one-year plants. There is some difference of opinion how far apart to plant. Some advocate three feet each way, and others two by four. I have always planted two feet between the plants and three feet between the rows, and about seven inches deep of a furrow, gradually filling in as the plants grow. A warm sheltered spot should be selected facing south, as this delicious vegetable is wanted in the Spring as early as possible.

Keep up successions of peas, planting at least every two weeks. Don't sow too thickly in the rows, as peas branch somewhat, and a better crop can be had if the seed is scattered thinly. We have found the variety called Pilot a fine pea for early use. Sow carrots, parsnips, beets, lettuce, parsley, as soon as ground will permit it. Onions that have been potted and hardened off well, can be planted outdoors about April first. Seeds of onions may be sown in March if ground is in a suitable condition.

Sow annuals for succession, especially the annual asters, as they are among the best of our cut flowers. The single-flowered type are by many preferred rather than the double ones. Personally I think they are more decorative.

Much forethought is required if a steady succession of flowers is to be kept up in the herbaceous garden. The colors that are most acceptable to the family are to be studied out, and an ample supply of plants has to be on hand to fill in. To keep herbaceous borders looking well throughout the season demands much labor and skill in grouping the plants. As plants go out of flower others have to be ready to take their places. If one is restricted to certain colors it makes it all the more difficult. Many plants have to be grown in pots, others can be transplanted from the supply garden. There are quite a number which can be dug up when coming in flower and transplanted into vacant spaces, if they are dry at the roots at the time of lifting, and given a good soaking of water after they are placed in position. These notes refer especially to annuals without which no herbaceous borders can be kept in color throughout the season. Such things as lilies and gladioli are better if pot-grown.

Rock gardens are becoming very popular and there are generally many positions where they fit in well. They, however, never should be attempted unless one has plenty of help at his command, as they have to be weeded by hand and those that do the work must be well posted on and plants used.

Roses may be pruned early in April. Hybrid perpetuals we prune back to two eyes. Where garden effects are desired they may be left much longer. With Teas and hybrid teas we only thin out the weak wood. Ramblers or hardy climbers need to be cut back to keep them within their allotted space, and all weak and useless wood removed; over crowding must be avoided.

Canterbury bells (*Campanula medium*) can now be planted where they are wanted in the border or in other places where they will be effective or useful for cut flowers.

Forget-me-nots (*Mysotis*), pansies, and English daisies (*Bellis*) that were Fall sown can now be placed in their flowering positions when weather permits. For Summer flowering pansies, sow the seed outdoors about the end of April and transplant to the flowering quarters when large enough to handle. Spring sown pansies last well through the Summer if well watered.

Any planting of shrubs can be done now; personally I have always had better success planting trees and shrubs in the Spring than in the Fall. They, however, need careful attention as regards watering throughout the Summer. As regards roses, unless they have been pot-grown, we always believe that on receiving them from the nursery, the best thing to do with them is to bury them in a trench, covering them with good damp soil for a week or ten days. Quite often they have been out of the soil for a long time and are somewhat shriveled. The burying process will plump up the wood. There is too much of the slap-dash method with many nurserymen. Sales seem to be what many of them are after so that not enough attention is paid to the goods delivered.

IN THE GREENHOUSE

In the greenhouse everything is now in more or less active growth. There will be many Spring plants in flower and the difficulty will be in retarding the flowering period of many things for later use. A light cool pit or a greenhouse facing north is almost indispensable at this season of the year. Acacias or other hard-wood plants that have finished flowering need looking over. If they are root-bound they require potting. I never like to trim them into shape until they show signs of starting into new growth and have gripped the new soil. Use a mixture of peat and good loam, if a good fibery peat is obtainable. If not, use plenty of half-decayed hard wood leaves, along with the loam. Avoid all use of lime in the soil, as hard-wood plants do not object to an acid soil, in fact, they do better in it. Any hard-wood plant that is not over well rooted is better if allowed to go a second year in the same pot, giving waterings with soot water alternately with Clay's fertilizer. Be careful never to overdo feeding hard-wood plants. Rain water is best for all plants and especially for the hard-wood shrub section. It is a pity that one does not see more often provision made for catching the rain water from the roofs of greenhouses and other buildings. A good waterproof tank should be made handy to the greenhouses, supplied with a motor, or gasoline-driven engine pump with pipes leading all through the greenhouses. An experienced eye can soon detect it in the general appearance and healthy look of the plants, especially the foliage. Many of the difficulties that one has with certain plants of the heath family and orchids might be overcome by the use of rain water.

Keep the young begonias of the Lorraine type, and the *Socotrana* tuberous rooted hybrids potted as long as they require it. Never allow them to get pot bound. Keep them growing in a temperature close to 65 degrees.

All bedding plants for outdoor work may be potted into 3½-inch pots the last of March. That size of pot will generally carry them over until such time as they are planted outdoors.

A batch of cuttings of *Euphorbia jacquiniæflora* may be secured and rooted at this time. Do not over-water these cuttings. Give them a good watering when they are put in and allow them to get fairly dry before another is given.

The prunings of the smaller wood of *Dipladenias* may be cut under two leaves about an inch long. These make excellent cuttings and treated the same as *Euphorbia*, root readily in a temperature close to 65 deg. Old plants of *Dipladenia* should now be starting into growth and may be potted if they require it. We run them two years in the same pot, after they are well rooted in size 7 in. Lack of success with *Dipladenia* is, as a rule, due to overpotting, and growing them under too heavy a shade in a hot humid atmosphere. We grow them in an old greenhouse that is never shaded and all Winter the temperature is never over 50 deg. Very little water is given during the Winter months, just enough to keep the wood from shriveling, which is generally about once a week when we syringe them, as they are subject to red spider. They flower with us from June until the middle of January. Cuttings rooted as advised above will flower beautifully in 3½-inch pots the first season. They delight in a good open compost of fibre, loam and chopped up roots of *Osmunda* fern, otherwise called orchid peat. Add some coarse bone and charcoal to the compost. We have a large plant in an 18-in tub which has not had a shift for three years. It is now starting well into growth, and after it is in full growth, we shall feed it twice a week, once with Clay's fertilizer and the second time with cow manure water, a good handful for an ordinary three-gallon watering pot.

Gloriosa Rothschildiana superba is another good Summer-flowering plant. Start singly in small pots, and when they have made a fair quantity of roots, five or six may be placed in a 12-inch pot. Use a compost of good rich lumpy loam with enough sand to keep it porous. When starting them in small pots, water very little until growth has commenced. A trellis has to be used to train them on, in any shape desired. *Gloriosas* require a night temperature around 60 deg., and should never have more than a very light shade over them.

Foliage plants in the tropical house will now be growing nicely, and careful shading is required on all bright, sunshiny days. Crotons require only a very light shade, just enough to keep the leaves from burning, otherwise one will get very poor colors on them. Airing in the tropical house has yet to be carefully done to avoid draughts. Damp the benches and floors well several times a day, and syringe the foliage well in the forenoon. Vigilance against insect pests must be exercised at all times, as nothing injures the beauty of the leaves more quickly. Palms may be fed liberally, if they have not been repotted this Spring. A night temperature around 55 deg. is best for them, as they make a much firmer and hardier growth, and can stand being moved around better when they are required for decorative work.

By April first many of the hardier annuals and plants that are to be used for planting out, may be transferred to cold frames. They can be aired more freely on all good days, preparing them better to stand up under outdoor culture, when the time arrives for planting them out. The Darwin Tulips can now be enjoyed. They do not like to be forced in a high temperature; 50-55 deg. is warm

enough for them overnight with a good airy atmosphere during the day.

Be sure and have a good stock of *Buddleia asiatica* for next year. It can be kept a long time in bud in a cool pit; and after *Stevia* has passed flowering, will take its place, both as a plant and as a cut flower. Keep the young plants potted along as they require it. Cuttings of *Stevia* may be also rooted, both the dwarf and tall growing varieties have their place in decorative work.

Some of the earlier flowering *Camellias* will be starting their young growths and should be fed with Clay's fertilizer and soot water. These plants do not like over-potting. See that they have free drainage.

Watch the shading in the orchid houses. Although they do not like full sunshine under glass from now on, as the foliage is likely to burn, yet they need all the light possible to ripen their growths for flowering, so that heavy shade has to be guarded against. A nice deep green on the foliage looks well, but good flowers are of more account. Orchids like to be grown near the glass. In fact, from my observations I find that all flowering plants do better the closer they are to the glass when growing. Why this it so I do not know, probably some of our scientific friends can enlighten me.

Cœlogynes, Chatsworth variety, has just finished flowering with us. This is one of the freest-flowering orchids, likewise one of the prettiest when in flower. *Cœlogynes* of this type do not relish disturbance at the root often, and therefore it is better to let them alone, until it is absolutely necessary to repot them.

The fine old *Cattleya Triana* is still flowering, also *C. S. Schroderæ*. As they go out of flower examine the condition of the roots, but do not disturb them unless the compost is in a rotten condition, or unless they have run over the sides of the receptacle. *Dendrobium Wardianum* will now need a warm moist atmosphere to develop next year's flowering bulbs. One of my neighbors has had fine success with this fine *Dendrobe*. He takes a small side growth from an old stem and in a year or two has a fine plant. He grows it in a rose house with practically no shade and feeds it with hen manure water. He certainly knows how!

Cymbidium are also flowering; they are among the finest of orchids, lasting a long time in flower. They grow well in the coolest part of an intermediate house. Pot them in a mixture of fern root, sphagnum moss and loam and do not over water.

Late flowering *Calanthes* will now need attention. Pot them as advised in last month's notes for the earlier ones. *Phalenopsis* are flowering with us. After flowering see that the compost is in a healthy condition. If it looks in a rotten state, remove as much of it as possible without breaking the roots and topdress with fresh material.

The grapes are all in a growing state. The earlier ones need thinning and those that have come along with the increasing heat of the sun will need disbudding. Keep the borders stirred up and give liberal application of food as the growths increase in vigor. Be sure and never overcrop, as it is much better to be on the safe side, when it comes to ripen the fruits.

Peaches may be syringed freely until the fruit approaches the ripening stage, as under glass they are liable to attacks of red spider. Feed them a little as the fruit is swelling. Disbud any superfluous wood on the pot fruit, retaining enough for next year's crop, and preserving the symmetry and shape of the plant. They need far more water and food than fruit planted out in a border.

Fig trees fruit well in pots. We have taken six nice fruits of *Brown Turkey* off a six-inch pot; the cutting was rooted the early part of the year and grown on a shelf

close up to the glass all Summer. They are gross feeders if grown in pots.

A busy season is ahead of us. Let us utilize all the knowledge gained by visiting our neighbors, attending flower shows and meetings for discussion, without which, and a liberal amount of reading, a gardener is very apt to get into a rut.

"THE LEAF-MINER IN BOXWOOD"

ABOUT a year ago the writer's attention was called to some Boxwood bushes that looked as if they had been Winter-killed. On careful examination he discovered that the cause of this appearance was due to a small maggot, or midge, securely housed between the two layers of the small leaves causing a blister-like surface. It is needless to say that he at once started a thorough investigation to find out just what this new trouble was, and the best means to combat it.

After a great deal of expense both in labor, and spraying materials that were supposed to destroy this new addition to our ever increasing list of plant-life enemies, and also causing an endless source of worry both to the owners and gardeners of large estates throughout the country, he feels safe to say that up to the present time all of the sprays recommended for this insect are of very little value.

You have only to study the life of the Boxwood leaf-miner, as it is now known, to understand that it is beyond the reach of any spray until it hatches out in the form of a fly, and then, to the writer's way of thinking, it is too late. The little success that has been gained in catching the full-grown fly with the various oil and soap sprays has been very small compared to the advance this insect has made during the past year.

The writer has personally inspected a great number of varieties of Boxwood on large estates where a great deal of money has been spent in labor and spraying materials, and today the bushes are as badly affected as some that were never treated. Then again you will often hear it said that this leaf-miner will not attack the Old English Box (*Buxus suffruticosa*). This is a great error, for while this insect does not appear to attack this variety as readily as some of the others, the writer has seen some very fine bushes of *Suffruticosa* badly affected.

On the other hand you hear the question from owners of fine Old Box bushes, that have been in the family for a great many years, "What can we do to save these old heirlooms? or are we to lose them?" Of course that seems a hard question to answer. But it can be answered, and answered with a big "No; you do not have to lose them unless you want to." It has been the writer's pleasure not only to know that the leaf-miner can be killed, but he has had it killed on bushes that were badly affected, and this was not done after it had hatched out in fly form, but while the maggot was between the two layers of the leaves. This was not a 65% kill, but a 98% kill, without any harm to bushes so treated.

The writer is well able to vouch for the above facts, and will be willing to answer any further questions on the subject to anyone interested.

Wm. Shaw, Elkins Park, Pa.

Live for something! Do good, and leave behind you a monument of virtue that the storm of time can never destroy. Write your name in kindness, love, and mercy on the hearts of thousands you come in contact with, year by year, and you will never be forgotten. Your name, your deeds, will be as legible on the hearts you leave behind, as the stars on the brow of evening. Good deeds will shine as the stars of heaven.—*Chalmers*.

Foreign Exchange Department

DAFFODILS AS CUT FLOWERS.—As in the case of other flowers, when there happens to be a profusion of bloom, there is in that of the Daffodil also the same danger of overcrowding taking place. Surely no better example of the beautiful is needed than is provided in the natural growth of these pleasing flowers, the foliage, in combination with the blossoms, affording an example of what to adopt when arranging the cut blooms. When growing and in flower the foliage and the blossoms seem to be, as they really are, quite indispensable the one to the other. Let this be imitated, then, as nearly as possible when disposing of the cut blooms, and afterwards, if need be, compare the natural style with the opposite or unnatural, of massing the flowers something in the same manner as they are sent to market in bunches, with which it is a rare occurrence for any foliage to be included, much as it is needed. Each flower should be so displayed as not to crowd upon that next to it; it is only in this way that the best possible effect can be had. Oftentimes when cutting Daffodils from home-grown plants there is a danger of two mistakes being made; the one is that of gathering too many sorts at once, and the other that of taking flowers which have been expanded for some time. It is not, perhaps, generally known that many who exhibit Daffodils in large numbers cut them before they are really fully expanded. Afterwards they continue to develop, but may not possibly reach quite to the size of blossoms still upon the plant; but invariably the color is slightly better unless shading is adopted.

Regarding the use of the foliage, it may be urged that to cut it largely would weaken the bulbs, but it may be taken a leaf here and a leaf there, so as not to make any perceptible difference, or where a good stock of the common Daffodil exists, its foliage can be taken in preference. To mix the different types is not desirable.—*Gardening Illustrated*.

STEVIA PANICULATA.—This delightful *Gypsophila*-like plant, sometimes known as *Stevia serrata* has been cultivated in France for a great number of years, whilst in the U. S. A. it has been an important florists' flower for more years than I can remember.

Some day, perhaps, growers and gardeners generally will wake up to the value of *Stevia paniculata* to follow *Gypsophila paniculata*. Seed is easily obtainable, and by sowing early the plants may be flowered in the open before frost occurs, or they may be lifted and planted to flower in early Winter like *Chrysanthemums*.

The roots are perennial, and if stored like Dahlias may be restarted the following season to flower very early.—*The Gardeners' Chronicle* (British).

PYRACANTHA GIBBSII. (Award of Garden Merit, November 27, 1922)—No trees or shrubs have more justified in 1922 their inclusion among garden plants than the well-known coral red *Pyracantha coccinea* (or *Crataegus pyracantha*, as it is still often called) and its beautiful variety *Lalandei*, with larger, more orange fruits, that come to us from Asia Minor and South Europe, but China has much more recently yielded some beautiful shrubs apparently nearly related to the Napalese representative of the genus, *P. crenulata*, but sufficiently distinct to warrant separate names, at any rate in gardens. It is difficult to say which is the most beautiful of these newcomers, and not all are yet widely known, but among them *P. Gibbsii* will certainly hold its own. Quick-growing to about 10 feet in height, with glossy dark evergreen foliage considerably larger than that of *P. coccinea*, making a tall, rather fastigate bush, flowering abundantly just after the Hawthorn ceases with dense bunches of white flowers, and never failing to bear great bunches of brilliant scarlet fruits as large as peas and contrasting beautifully with the foliage from October to December, this is a species worthy and capable of filling a place in any garden. The seeds grow freely, and may give rise to forms differing somewhat in the shape of the leaves, the exact shade of the ripe fruits, and the precise time of ripening, but all alike worth growing; and if it be desired to propagate any one of the forms it may readily be done, either by cuttings or by layers.—*Gardening Illustrated*.

THE RUSSIAN VIRGIN'S BOWER (*Clematis Tangutica*).—This commands attention from all points of view, owing to the profusion and rich color of its flowers. Like many other shrubs, this alters its character after the first few years, and instead of the elegant, frail plant so beautiful and refined during that period, it becomes a strong, rampant grower more suited to clothing the sides of a pergola or large tree stump where its long garlands of flowers may droop to their full extent, displaying their graceful charm in that beautiful loose manner so much admired by all lovers of picturesque gardening. It is the most striking of

all the yellow-flowered Clematises, and although occasionally referred to as a variety of the well-known *C. orientalis*, it is— from a garden point of view—totally distinct and a vastly superior plant in every way. It is a native of Central Asia and appears to have been first introduced to Kew from St. Petersburg in 1898.—*Gardening Illustrated*.

A NEW BUDDLEIA.—*Buddleia alternifolia* is a widely branched and vigorous shrub, producing during June quantities of rich lilac-purple blossoms on the growths of the previous year, so that one cannot prune it in March as is done with *B. variabilis* varieties. Introduced by the late Mr. Reginald Farrer from Kansu, the dainty yet luxuriant growth of this *Buddleia* is in marked contrast to the vigorous shoots of *B. variabilis*.—*The Garden*.

DEPARTMENT OF BOOK REVIEWS

DECORATIVE PLANTS, TREES AND SHRUBS, by F. J. Fletcher, F. R. H. S. Benn Brothers, Ltd., London.

This concluding volume of the series of six volumes, coming, as have the others, from the experience of an unusually successful nurseryman, is, even more than the preceding five of these books, justly entitled to the consideration of propagators of plants in America. It is even delightful reading, for, more than the others, it gives scope to the æsthetic ideals of its author. In the midst of his enthusiastic appreciation of the beauties of plants grown for ornament he is nevertheless consistently practical. At only one point does his zeal carry him away; in dwelling upon the charms of the hybrid lilacs he has forgotten to tell how to propagate them. But in other matters, particularly those relating to the propagation of plants the importation of which into the United States has been nearly altogether cut off, the treatment is such that every horticulturist would find at least useful suggestions. The management of cuttings is set forth with all necessary details the disregard of which makes our hurried American methods successful only in part.—F. B. M.

WINTER BOTANY, by William Trelease, Professor of Botany in the University of Illinois. Published by the author at Urbana, Illinois.

This is a companion to "Plant Materials of Decorative Gardening," designed to aid in identifying the same woody plants, except the conifers, in Winter. It is extraordinarily compact, composed with precision, each subject beginning a new page and clearly illustrated by an accurate drawing of the parts distinguishing it most. In the use of the keys attention is called to an amazing number of points of difference which lead to fine appreciation of the structure of the plant under examination. Much more than in the other work there are remarks concerning the history of many of the plants and concerning their peculiar properties of one kind or another. Some of these remarks are of a character to interest the horticulturist and the gardener.—F. B. M.

HORTICULTURE FOR SCHOOLS, by the late A. V. Stubenrauch, Milo N. Wood and Charles J. Booth. The Macmillan Company, New York.

Although the actual composition of this latest addition to the Rural Textbook Series is the work of two Californians it gives unmistakable evidence throughout of having for its foundation the material assembled by the deceased senior author, his method and his point of view. His post-graduate studies were taken at Cornell University and he served for a time at the University of Illinois and in connection with the pomological work of the United States Department of Agriculture. It furthermore has had the careful oversight of Professor Bailey, and among several other coadjutors there has been one from the West, one from the Central West and one from the Southwest. But it has not been made too learned in the sense of being prolix, ponderous or abstruse. On the contrary, it is, for contents, general arrangement, method of presentation and completeness most admirably adapted to the purpose for which it was designed, that of serving as an elementary text-book in schools and in reading courses.

The part devoted to the Use of Ornamental Plants was necessarily made very summary; while the enumeration of ornamental material is sketchy and is far from being an approach to completeness, the condensed statement of the principles of landscape design is happily sound. The entire work is accurate and reliable, with but few minor exceptions, such as failing to observe that it is only *Berberis vulgaris* and its varieties and not the oriental that are intermediary hosts of the common wheat rust and such as referring to pepper plants as hardy.—F. B. M.

TENTH INTERNATIONAL FLOWER SHOW
GRAND CENTRAL PALACE, NEW YORK, N. Y.
MARCH 12-17, 1923

Do not overlook this important horticultural event

National Association Of Gardeners

Secretary's Office, 286 Fifth Ave., New York

1923 Convention, Pittsburgh, Pa. (Date not decided.)

The aims of the association are to elevate the profession of gardening by improving conditions within it.—To cement a closer bondship among all engaged in, and interested in, gardening—to create a greater confidence between employer and employee.

Co-operating with the Massachusetts Agricultural College, the association conducts a course in training young men for the profession, whereby they obtain theoretical knowledge as well as practical experience.

OFFICERS 1923

President JOHN BARNET, <i>Sewickley, Pa.</i>	Vice-President WILLIAM GRAY, <i>Newport, R. I.</i>
Secretary M. C. EBEL, <i>New York, N. Y.</i>	Treasurer MONTAGUE FREEMAN, <i>Brooklyn, N. Y.</i>

TRUSTEES (For 1923)—Thomas W. Head, D. L. Mackintosh, Arthur Smith, New Jersey; Robert Cameron, Massachusetts; Andrew L. Dorward, Rhode Island.

DIRECTORS—(To serve until 1924) William Hertrick, California; George H. Pring, Missouri; Robert Weeks, Ohio; Thomas Wilson, New York; Harold Bryant, Connecticut; Harry Cartwright, Michigan; H. Ernest Downer, New York. (To serve until 1925) George Wilson, Illinois; James Stuart, New York; William Kleinheinz, Pennsylvania; Edwin Jenkins, Massachusetts; Carl N. Fohn, Colorado; Joseph Tansey, New York; John Tonkin, Pennsylvania. (To serve until 1926) Alexander Michie, New York; George F. Stewart, Massachusetts; Theodore Wirth, Minnesota; George W. Hess, District of Columbia; R. P. Brydon, Ohio; William C. Rust, Massachusetts; Charles Schrrall, Wisconsin.

SUSTAINING MEMBERS

New York—Mrs. J. J. Albright, Mrs. Robert Bacon, George F. Baker, Edwin S. Bayer, Henri Bendel, Albert Clayburgh, W. R. Coe, Mrs. F. A. Constable, Paul D. Cravath, Mrs. W. S. Firestone, Mrs. Francis F. Prentiss, John L. Severance, H. S. Sherman, H. L. Thompson. *Michigan*—J. B. Schlotmann, E. D. Speck. *Indiana*—Theodore F. Thieme. *Illinois*—A. Watson Armour, Harry B. Glow, A. B. Dick, Clayton Mark, Mrs. Julius Rosenwald, Mrs. F. W. Upham. *Minnesota*—Mrs. Chester A. Congdon, F. H. Stoltze. *Iowa*—Mrs. G. B. Douglas. *Missouri*—August A. Busch, Dr. George T. Moore. *W. Virginia*—Mrs. Arthur Lee. *Georgia*—Asa G. Candler, Jr., G. Gumby Jordan. *South Carolina*—Robert S. Mebane.

LOCAL BRANCHES

NEWPORT, R. I.: Andrew L. Dorward, chairman; Frederic Carter, secretary.

ST. LOUIS, MO.: George H. Pring, chairman; Hugo M. Schaff, secretary.

NASSAU COUNTY, L. I.: James Duthie, Oyster Bay, chairman; John McCulloch, Oyster Bay, secretary.

BOSTON, MASS.: Robert Cameron, Ipswich, chairman; W. N. Graig, Weymouth, secretary.

WESTERN PENNSYLVANIA: Manus Curran, Sewickley, chairman; Henry Goodband, Sewickley, secretary.

WESTERN PENNSYLVANIA BRANCH

A meeting of the members of the Western Pennsylvania Branch of the National Association of Gardeners was held in the Carnegie Library, Pittsburgh, on Tuesday, February 20. Manus Curran, our chairman, was unable to be present on account of illness, and John Barnet was elected chairman for the evening. A. F. Frishkone and David Fraser, the committee appointed to make inquiries regarding accommodation at hotels and a suitable convention hall, reported in detail.

It was decided to hold the convention on August 14, 15, 16 and 17 at the Fort Pitt Hotel, subject to the approval of the Executive Board.

George W. Burke, superintendent, Bureau of Parks, Pittsburgh, was endorsed by this branch for membership in the

National Association. Neil McCallum gave a short but interesting talk on "The Willful Destruction of Wild Flowers, Trees and Shrubs," using as an illustration "The Wild Flower Gatherers" as illustrated and reprinted in the February CHRONICLE. This branch feels the public should be educated along these lines. The chairman announced the following chairmen of convention committees:

General Chairman—Manus Curran.
Chairman of Publicity—John Carman.
Chairman of Banquet—August Frishkone.
Chairman of Lecture—Neil McCallum.
Chairman of Traffic—Wm. B. Thompson, Jr.
Chairman of Entertainment—David Fraser.
Chairman of Programme—Henry Goodband.

The next meeting will be held on Tuesday, March 20, at Sewickley. Plans are well under way for the annual convention at the Fort Pitt Hotel, Pittsburgh, next August, and the various committees hope to be able to make a detailed report at this meeting. We ask all members and friends interested to show their co-operation by attending.

HENRY GOODBAND, Secy.

THE BOSTON BRANCH

A meeting of the Boston Branch of the National Association of Gardeners was held at Horticultural Hall, Boston, Friday evening, March 2. Robert Cameron presided and about forty members were in attendance, some having traveled thirty to forty miles to attend the meeting.

President Cameron, on request, read a paper which had been reported in part in THE GARDENERS' CHRONICLE OF AMERICA and some other papers, and in full in one trade horticultural journal. He read also a number of letters received since the New England Nurserymen's Convention, all in hearty commendation of his stand. He read extracts from discussions and editorials on the same subject, some of them written over twenty-five years ago, showing a desire at that time on the part of professional gardeners to drive unworthy, unscrupulous and fraudulent men from their ranks, who are not true gardeners at all but impostors. Mr. Cameron thought the drummers were a perfect nuisance, and that seedsmen might well advertise more, and keep their men at home.

A long and animated discussion followed Mr. Cameron's paper, and among those participating were George F. Stewart, James Methven, Walter H. Golby, James Donald, W. N. Craig, Andrew K. Rogers, P. J. Van Baarda, Stewart Forbes. A number of members warmly defended the drummers and considered them a necessity; others felt that New York and Boston seed houses send men out on the road far too much, so that drummers become a nuisance. The "graft" question was considered at length, and it was the opinion of practically all present that there was very little of it prevalent among gardeners, and that the offenders were in nearly all cases men who were not trained gardeners at all, but hired at a cheap rate by employers, unwilling to pay a fair salary such as a competent man commands.

Mr. Cameron was given a hearty vote of thanks, and it was voted to hold another meeting on the afternoon of April 6, the second day of the Boston Spring Flower Show.

W. N. CRAIG, Secy.

A NEW BRANCH PROPOSED

Thomas W. Head, a trustee of the National Association of Gardeners was invited to address the Monmouth County Horticultural Society on February 15, on the subject of the National Association of Gardeners, its aims and achievements. Mr. Head spoke before a well attended meeting and as former President and Treasurer of the National Association, he was able to present some interesting data from the beginning of its reorganization through its gradual rise to the prominence it has now attained. Mr. Head mentioned the co-operative spirit that has developed between the Garden Club of America and the Association and some of the discussions which have been held at the conventions of the Garden Club concerning the profession of gardening and the association which represents it. He also spoke of the interest manifested by estate owners in entertaining the visiting gardeners on their estates, at the time of the annual conventions. Mr. Head referred to the training course which has been established in the Massachusetts Agricultural College through co-operation between the college and the association. In general he reviewed the hard road which the association at times had to travel and how it persevered until today it ranks as one of the foremost organizations of horticulture in the country. All in all the meeting was a most successful one with enthusiasm aroused and the general feeling created that a local branch should be established.

Mr. Head was also invited to attend the monthly meeting of the Elberon Horticultural Society on March 2 to repeat his talk on the National Association of Gardeners which he gave before the

Monmouth County Horticultural Society. Quite a delegation accompanied Mr. Head to Elberon from the latter society and the attendance at the meeting was very representative of the "old timers" and the younger element of the profession. William Waite, William Turner, Edward Regan and Alfred Millard were noted present among the gathering. The talk which was practically the same as above outlined was well received. Several members entering into the discussion which followed, remarked that they had no idea that the association had been doing and is doing such great work, and that it stood for such good things in the gardeners' interests. A number present, not members of the association, signified their intention of becoming members. The general sentiment was that the Elberon Horticultural Society should unite with the Monmouth Horticultural Society in forming a branch of the National Association of Gardeners. It was decided that immediately following the New York Flower Show such an organization should be undertaken.

CLEVELAND BRANCH

A meeting of the members of the National Association of Gardeners residing in the Cleveland district, was held at the Alhambra Restaurant on Monday, March 5, to consider the organizing of a local branch. Robert Bryden occupied the chair.

John Barnet, of Sewickley, Pa., president of the National Association of Gardeners, spoke at length on the advantages of local branches, and gave in detail the object of the association. A general discussion followed, the members present being unanimous in favor of forming this branch. Several members unable to attend, wrote expressing their approval.

The next meeting will be held at the Alhambra Restaurant on May 7 at 7 P. M.

GEORGE WYATT, Secy. pro. tem.

NASSAU COUNTY BRANCH

A meeting of the Nassau County Branch has been called for March 14 at 6:30 P. M. in Pembroke Hall, Glen Cove, prior to the regular monthly meeting of the Nassau Horticultural Society which will convene at 8 P. M. at the same place. The branch meeting will be reported in the next issue of the CHRONICLE.

NEW MEMBERS

Active members: Geo. W. Burke, Pittsburgh, Pa.; Victor Hunt, Glen Cove, L. I.; Joseph Strachan, New York City; Lester G. Bennett, Lake Mahopac, N. Y.; Thomas McConnell, Chauncey, N. Y.; Casper Fred Weber, Rutherford, N. J.; B. A. Myers, Chagrin Falls, O.; James M. Adie, Boston, Mass.; Walter Davey, South Braintree, Mass.; Wm. Keith, South Hamilton, Mass.; William Shaw, Elkins Park, Pa.

AMONG THE GARDENERS

Ernest Grey has accepted the position of gardener to Mrs. Arthur Lee, Elkins, W. Va.

George Walker secured the position of gardener to Mrs. Stephen Leonard, East Hampton, L. I.

Martin Kuiper has accepted the position of superintendent to Frank B. Black, Mansfield, Ohio.

Harry Cartwright has been placed in charge of the Country Club of Detroit, Grosse Pointe Farms, Mich.

George Baker has accepted the position of superintendent on the Reginal Dix estate, Greenwich, Conn.

William I. Martin for forty years gardener on the Nathaniel T. Kidder estate, Milton, Mass., where he had care of one of the finest collections of rose trees and shrubs and

A CARPET-LIKE lawn adds much to the value of a fine home. Ideal Power Mowers maintain such lawns at low cost by cutting them evenly and rolling them to velvety smoothness in one operation.

Your caretaker or an unskilled man at laborer's wages can do perfect work with an Ideal. He can cut from a half to a full acre an hour, trimming the borders closely. Contrast this with the cost of mowing, rolling and trimming your lawn by hand and you will readily see why an Ideal pays for itself so quickly.

We will be pleased to send you interesting literature and prices upon request.

Ideal Power Lawn Mower Company

green house plants in Boston, died on March 2, following an attack of appendicitis. Mr. Martin was born in Bristol, England, about seventy years ago, and came to this country when quite a young man, after good training on prominent estates over there. For many years he was one of the largest and most successful exhibitors of plants and flowers at the shows of the Massachusetts Horticultural Society, when like David Allen, Wm. Robinson, C. M. Atkinson, James Cauley and other were in their prime.

INTERNATIONAL FLOWER SHOW

As this number goes to press, everything indicates that when the Flower Show opens its doors on March 12 it will present to the public a floral display that has so far been unsurpassed at the Grand Central Palace.

Competition will be keen in the classes of the big gardens as well as in the rose and

numerous other classes. The members of the Garden Club of America are manifesting lively interest in the classes of table decorations and in the miniature or model gardens. Nothing has been left undone by the various committees to assure the success of the 10th, International Flower Show. It will be fully reported in the April issue of the GARDENERS' CHRONICLE.

LOCAL SOCIETIES

SOUTHAMPTON HORT. SOCIETY

The sixteenth anniversary of the founding of this society was celebrated by a turkey supper, furnished by the ladies of the Presbyterian Church. A large number, over two hundred, attended and the whole affair

was a complete success. The members deserve credit for their arrangement, and certainly the ladies of the church are well entitled to all honor and praise for the efforts put forth by them to arrange and serve the abundance provided for the feast. Everybody seemed to be happy.

President George Campbell called the assembly together, calling upon Benjamin C. Palmer to ask the blessing, and the ladies of the church proceeded to serve the turkey.

After the feast, President Campbell again called upon Mr. Palmer, who was one of the charter members as well as the society's secretary for the first several years, to speak. Mr. Palmer spoke on "Reminiscences," telling how the society was thought out, and the thought carried into effect by Herbert W. Clarke, one of our first professional gardeners. He interested a few others and a meeting was held in January, 1907, in the carriage house of James L. Breese, at which sixteen gardeners were present. The second meeting, twenty-five in attendance, was held in a barrack of a room in Agawam Hall, the only place available at that time. There the society was formed, officers elected, and the Southampton Horticultural Society was in running order and ready for business. Later on they moved to more agreeable quarters in Odd Fellows' Hall, where they still hold forth. The other speakers were Stanley R. Candler, present financial secretary, and Mr. Marshall, a past president.

WESTCHESTER AND FAIRFIELD HORT. SOCIETY

The regular monthly meeting was held in Greenwich, Connecticut, February 13. Some very good exhibits were shown. Edwin Beckett exhibited a very choice vase of Laddie carnations, receiving first prize and a cultural certificate. Second prize, vase of Buddleia Asiatica, went to William J. Sealey and third prize, vase of Antirrhinum, Torchlight, to Alex Smith. Other exhibits included vase of Laddie carnations, W. D. Robertson; vase of sweet peas, James Stuart; vase of calendula, W. D. Robertson; vase of stocks, Alex Smith; John Andrews received first in fruit for four varieties of apples.

Silver and bronze medals were awarded to those receiving highest score of points in both flower and vegetable exhibits during the past year. William Smith received first for flowers; H. F. Bulpitt, second. For vegetables, James Linane received first; H. F. Bulpitt, second. Silver and bronze medals will be given in both classes for exhibits during this year. Through the generosity of A. N. Pierson, Inc., and John H. Troy, the usual monthly prizes will be awarded again this year. The executive committee plans to have a lecture for every meeting of this year.

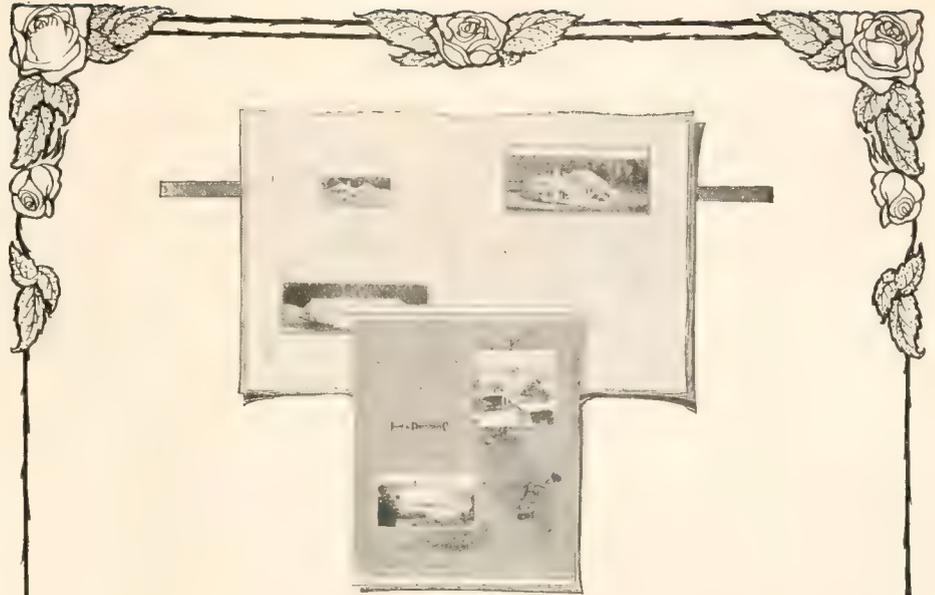

Mr. Underhill, of Boston, will give an illustrated lecture on, "Old New England Gardens," in May. The Garden Clubs of Greenwich, Rye, and Riverside are to be guests at this lecture.

A lecture on "Bees and Bee Keeping," was given by Mr. Vanderwarken. H. B. Reed, fruit expert, gave a very interesting talk on "Spraying of Insect Pests and Diseases of Fruits." Specimens of diseased fruits and bark were passed around to illustrate his topic. At the conclusion of business a social half hour was enjoyed.

A. KNEUKER, Cor. Secy.

NASSAU CO. HORT. SOCIETY

The monthly meeting of the above society was held in Glen Cove on February 14. Vice-president Thomas Scott occupied the chair. Peter Morrisson, of Glen

Of Special Interest To You Would-Be Greenhouse Possessors

With greenhouses, as with autos and most other things, there are a certain few that are favorites.

Year after year those same favorites have continued to be favorites. Such being the case, then, there must be certain very logical reasons for it.

Reasons that will appeal to you quite as they have to others.

Appreciating such, it's a wonder we hadn't thought long ago to bring these favorite greenhouses together and make a special little catalog of them.

However, we have done it now. Done it in a most attractive way

that am sure will appeal to you and your love of flowers and growing things.

Five favorites are shown, among which unless we are greatly mistaken, you will find just the greenhouse that best suits your needs and fits your pocketbook.

There are plenty of photos of both exteriors and interiors, besides plans and ample description.

So complete is it, that without any further ado, houses have been purchased directly from it.

Mayhap you will do the same.

You are most welcome to a copy of this new Glass Garden Catalog.

Cove, was elected to active membership. William Cullen, William Milstead and James McCarthy judged the exhibits. Their decisions were: Six sprays of stocks, first, J. W. Everitt. A very fine vase of sweet peas (Rose Queen) exhibited by J. W. Everitt was awarded a cultural certificate. The Michell Seed House medals awarded for achievement in horticulture were presented to James McCarthy, Ben Sutherland, Charles Stango, Thomas Meech and Thomas Bell. William Sperling was in fine form in his talk on the advancement of Nassau County. If we were to believe all "Billy" tells, this must be the promised land. Fred Piper spoke about the Morristown Horticultural Society. Letters were received from Bobbink & At-

kins regarding the recent rose catalog they have issued, and from the secretary of the Chrysanthemum Society giving its definition of terminal spray as applied to single and hardy mums. Exhibits for March 14th meeting will be 12 white, 12 pink and 12 mixed carnations.

ARTHUR COOK, Cor. Secy.

ELBERON HORTICULTURAL SOC.

The above society held its regular monthly meeting March 5, President G. Masson occupying the chair. T. Clark, Charles Stout, Walter Lindhardt, John Koster and George Sodemann were elected to active membership. A fine attendance was on hand, with

a good delegation from Monmouth Horticultural Society. Some excellent exhibits were shown. The judges selected were: L. Kennedy, William Waite, and William Turner. The President introduced Thomas Head, who gave a very instructive and helpful essay on the National Association of Gardeners. W. Waite also spoke on the same subject, after which a general discussion was entered into by the society. The President spoke with regret of D. Gustafson, active member, leaving this section for a position on the Hudson. The April meeting will be a ladies' night when a good time is expected for all.

WILLIAM WILLIAMS, Secy.

HORTICULTURAL JOTTINGS

The General Federation of Women's Clubs is conducting a campaign for the observance of a National Garden Week, April 22 to 28, inclusive, which plan has received the personal approval of President Harding.

Programs may be secured by addressing Mrs. John D. Sherman, General Federation of Women's Clubs, 1734 N street, N. W., Washington, D. C.

Two large bouquets of flowers were found in Tut-ankh-Amen's tomb in the Valley of the Kings. This Egyptian monarch was placed in his funeral chamber thirty-five centuries ago and the doors were sealed. When an English explorer opened the tomb, he found the funeral flowers still intact.

Here, in truth are the flowers of yesterday. According to the cable dispatches, they were not arranged in wreaths or in any of the floral designs customary at modern funerals, but in the form of bouquets, such as might be carried by a woman.

An attempt is being made to coat these flowers with wax and preserve them for public exhibition. These funeral flowers are a touch of sentiment, proving how constant human nature is. With all the outward changes that have taken place in the affairs of man since Tut-ankh-Amen reigned, men and women have the same passions, the same hates, loves, and fears, the same hopes, ambitions, and desires. Nothing found in the tomb of the Valley of the Kings indicates that the basic motives of human nature have materially changed. Nor has its basic love of beauty.—*N. Y. Evening Mail.*

The fifth oldest known living thing on earth, and the third oldest in North America, is a giant cypress tree in what is known as the Edenborn Brake, in Winn parish, this State, according to Carlton F. Poole of the Louisiana State Convention Department.

The age of the tree has been placed at 2,500 years by Prof. Herman Schrenk of St. Louis, and other scientists who have examined it. According to records, it is exceeded in longevity only by the Santa Maria del Tule cypress, near Oaxaca, Mexico, 5,000 to 6,000 years old; the Dragon tree at Orotava, Island of Teneriffe, 4,500 years old, the Redwood tree, California, 4,000 years old, and the Baobab tree, Senegal, 4,000 years old.

The Edenborn cypress was budding into life when Jerusalem was taken by Nebuchadnezzar. It was a lusty young sprout when the battles of Marathon and Thermopylae were fought, when Assyria was at the apex of world dominion and when Rome was a village of mud roads and hovels. The tree was 600 years old when Christ was born in Bethlehem, a veteran when the Roman legions were withdrawn from Britain to leave the savage tribes of those islands to fight out their differences, and was more than 2,000 years old when Columbus sailed into the Atlantic to begin his voyage of discovery.

The tree was one of a number of its kind in a tract of pine timber purchased by William Edenborn some years ago and when logging began he refused to permit it and

GREEN PEAS from June till August!

Do You Know This Secret?

A bountiful succession of this toothsome delicacy is yours if you follow these simple directions

Plant this collection of 6 choice varieties *all at once* this Spring, just as soon as the frost is out of the ground and they will mature in the order named—producing a steady procession of big mouth-watering crops from about June 20th till late in August.

The reason for this is evident. Peas must develop their roots in cool weather and so are able to supply sufficient moisture to leaf, flower and pod, as they rapidly multiply under the summer sun. On the other hand late planted peas are almost always a disappointment, as every experienced gardener has reason to know.

Here are varieties

- | | |
|--|---|
| 1. Schling's Pedigree Extra-Early. 2½ feet. The earliest Pea grown; large, well filled pods. | 4. Dwarf Champion. 2½ feet. An enormous cropper. Broad pods, very sweet Peas. |
| 2. Gradus, or Prosperity. 3 feet. An early fine wrinkled Pea of delicious flavor. | 5. Improved Telephone. 5 feet. Enormous pods, filled with Peas of the finest quality. |
| 3. Sutton's Excelsior. 1½ feet. The most productive of dwarf medium-early wrinkled Peas. Very sweet. | 6. Heroine. 4 feet. Pods are large, deep green, somewhat curved; tender Peas of finest quality. |

three others almost as large to be felled, although the giant contains approximately 23,000 feet of lumber. It is peculiarly situated for one of its species, for while the cypress usually grows in swamps the Edenborn specimen stands in a hollow between hills.—*N. Y. Herald.*

One point about wild flowers is their wide-flung profusion. A garden flower claims seclusion; the wind is not welcomed in a garden but he is the rough-and-tumble playmate of every wild flower, and the level wheat fields ripple with laughter as he goes frolicking by.

Numberless as the stars are the wild flowers. Who has not brushed the gold from a million marguerites, their ranks closing behind you as though you had never passed that way? Nor does the fragile primrose know aught of scantiness. She pushes her pale petals to the surface, parting the leaves to take an early peep at the sun. She bedecks the woods and embankments and dapples the shade with her light. And what of the English bluebells? Fragrant, tapering bluebells so thickly beneath the beeches and oaks that it is quite impossible not to crush them as you walk through the woods in May. Another rare vision, too, when on a Spring evening the full moon sheds a bright sheen all over a field of buttercups. A vision of gold and silver, renewed and ever renewed in memory.

In the Highlands there is the wild beauty of the heather, splashing the hills and moors with its magenta blaze; masses of it surging at the base of gray-lichened boulders, wooing the coveys of furry-footed grouse to slant into its depths with downward curving wings.

Yet, it is sweet to stand quietly in a sheltered garden, with intimate flowers, named and natured, rising in orderly array at one's feet; yet sweeter still to push out into the open and revel in profusion.—*C. S. Monitor.*

French wine growers are tearing up their vines and planting the hillsides with potatoes and grain, according to a committee just returned from a survey of the principal grape regions. This is ascribed directly to the loss of markets in the United States and in Sweden, as well as the failure of access to German and Russian trade.

The growers declare their cellars cannot hold another million bottles, and are planning to organize a great sales co-operative society which will dispose of the stocks accumulated in the last five years at reasonable prices, enabling the industry to start over again, better calculated to comply with the world market next year.—*N. Y. Herald.*

WHY THE TOMATO WAS FORMERLY CONSIDERED POISONOUS

The Tomato, which in these days occupies such a prominent place in our food menus, was until comparatively recent years, believed to be poisonous. This was in a way natural, from the standpoint of the botanists, because they knew that the Tomato plant was really a member of the poisonous "deadly nightshade" family, as is also the familiar Irish potato.

This belief as to the poisonous nature of the Tomato was so prevalent that even after a few venturesome folk decided they must be good to eat, they took the precaution of stewing them first. When no harm resulted it was believed that the stewing process extracted the poison. But even when other more venturesome folk, who perhaps were so hungry they were willing to try anything, ate raw Tomatoes, without harmful result, it was a long time before the practice became common.

Before 1830 the Tomato was known as

Therefore It Hath Its Charm

Isn't it hard to quite understand how some people spend unstintedly for buildings and the "doing over" of their grounds, only to secure a regrettable effect of man-madness?

Everything has the look of having been just placed there. All nature's naturalness has been ruthlessly ironed out. In contrast, you at rare intervals run across a layout that is a delight in its utter frankness—its skillful adaptation to nature's own setting.

How it prompts a long breath and a sigh of contentment.

Therefore, this greenhouse has its charm.

It just fits in the picture, as it were.

You can well imagine the satisfaction it was to do our bit in securing this result for Dr. J. H. Lancashire on his Massachusetts woodland-crested estate, at Manchester-by-the-Sea.

Why can't we do as much for you? Would you like our booklet called "Owning Your Own Greenhouse"?

If you want the finest
DAHLIAS

the Giants—true to name—we have them.

the "love apple" and the plants were placed in gardens for decorative purposes only. The fruit was then no larger than a small Plum or large Cherry. Tomatoes of the size now popular are the result of cultivation. The use of Tomatoes as food did not grow until after Civil War times. Today, in the United States alone, some 300,000 acres are devoted to Tomatoes, and the annual crop, most of which is canned or made into catsup, amounts to almost one million tons. It is the third in value of the vegetable crops. *Philadelphia Lett.*

THE LACE FLY

The Rhododendron bug or lace fly, *Stephanitis rhododendri*, was first found on our native *Rhododendron maximum*, but infests both hemispheres. These small insects attack all the Rhododendrons with the exception of *R. Smirnowii*, which has leaves the under part of which are covered with a felt-like substance that repels the insects. The Mountain Laurel and other *Kalmias* suffer from attacks of the pest, and the flowering quinces are occasionally infested.

In the eastern states this pest has two broods. The first one will appear just before the flowers of the Rhododendrons and *Kalmias* open, and the second about the end of August. Plants infested by this insect can be readily determined by the discoloration of their foliage.

In the dormant stage (November to beginning of May) the under side of the leaves are dotted with coffee-brown spots along the main mid-rib of the leaf, which indicates the presence of the eggs from the second brood, which will hatch just before the flowers open.

During the Summer months the leaves are covered with a sticky substance, and numerous black shiny spots which are the excretions of the insects present. The upper surface becomes dull green, and spotted a greenish yellow throughout. Plants which have this appearance are usually badly infested. In extreme cases of infestation the Rhododendrons and *Kalmias* will drop their foliage early in the Fall, with the exception of the leaves produced during the Summer's growth, which will be one-third the normal size and are usually not sufficient to keep the plants alive after another year's injury.

Rhododendrons and *Kalmias* which grow in an open, sunny situation are mostly attacked by the fly, whereas the ones which grow near the water, on a northern slope, or shaded by hemlocks or other tall evergreens from the hot sun, are very seldom injured.

In the early stages of life the insects have no wings, but have the appearance of lice. They usually congregate in small numbers or crawl slowly over the under surface.

After two or three weeks wings begin to appear, and at a touch on the branches many insects will fly away. Then your spraying will have little or no results. The time to spray Rhododendrons is just before the flowers burst open. Do not delay until the *Kalmia* flowers open, for that will be too late to catch the first brood. The second application must be made about the middle of August. The main point is to have as much pressure as possible and the spray must be applied thoroughly to the under side of the leaves. A hand or a power nozzle is the best; it can be attached to a four- or six-foot extension rod.

Remember the following:

First, this is a sucking insect. It must be hit hard with the spray, the more force the better.

Second, always spray on the under side of the leaves.

Third, use a power nozzle with a forty-five degree angle, attached to a six-foot rod.

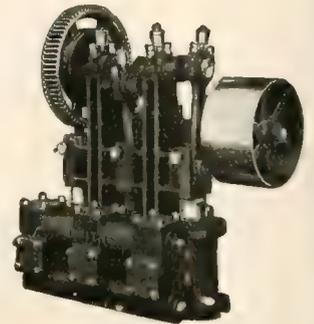

—*Horticultur.*

Beautiful Lawns and Gardens

—require a water system of sufficient capacity and stamina to deliver an abundant, un-failing supply of water.

At the residence of Mr. Alexis L. Ehrman at Atherton, California, a compact Deming Triplex pump of 91 gallons per minute capacity supplies this beautiful country place with all the water needed for house requirements, for spacious grounds, and fire protection at very economical operating cost.

Deming Triplex Pump used on the Ehrman estate.

MOUNT ATLAS SILVER CEDAR

For a position where a single specimen of an uncommon evergreen tree is wanted, the recommendation of the Mount Atlas Silver Cedar (*Cedrus Atlantica glauca*) is sure to meet with approval. Although having the appearance when small of being apparently sparse of branches and foliage, it will attain to its compact and shapely habit as it grows older, and to which we may add the pleasing silvery blue of the needles. The latter characteristic is admired and preferred by many to the more pronounced blue of the Koster's Spruce and it has the additional advantage of being a far less common tree.

The arrangement of the leaves on the Mount Atlas Cedar in tufts or clusters (fasciculate) distinguishes it from such common evergreens as Firs and Spruces, which have the same conical habit of growth, but it resembles the foliage of the Larch.

The prospective purchaser may not be aware that *Cedrus Atlantica glauca* is a true Cedar, cone bearing, and should not be confused with the species of *Juniperus* which are also known as Cedars (*J. virginiana*, the Red Cedar, being the most notable example) nor with the *Retinisporas* or *Chamaecyparis*, which are also referred to as Cedars.

There is no question of the hardiness of this blue form of the *Cedrus atlantica*, it being regarded as even hardier than the type, so the collector may plant both with impunity.

Another species in this form might well be included to make a pleasing group, for although slightly less hardy it will do well if planted on high ground. For Southern locations we would also urge including in the group *C. Deodara* (not hardy in the North) and thus complete an interesting collection of the three species of this genus of true Cedars. Seed, sown in Spring, is the usual method of propagation, although grafting is necessary with the varieties.

Perhaps we should caution against pruning these Cedars, except for the removal of interior interfering branches, for if the leader is removed it is difficult to make another and the tree will not assume the symmetry of a single shaft.—*Florists' Exchange*.

If You Are Engaged in the Pursuit of Horticulture Whether for Pleasure or for Profit

you cannot fail to be in the Gardeners' Chronicle of America, for, as you will observe by studying its columns, it is devoted exclusively to the science of floriculture and horticulture.

AXFIXO The Superior Nicotine Dust

KILLS aphids, thrips, white fly, mealy bug, red spider, acacia scale, leafhoppers, ants, cucumber beetles, and most soft bodied insects. AXFIXO is a highly volatile nicotine dust evolving pure nicotine gas when exposed to the air. This gas envelopes the entire plant. It goes where liquid sprays and smoke cannot possibly go.

Packed in 1, 5, 25, 50, 100 pound containers.

Ask your dealer for AXFIXO, if he cannot supply you, write the manufacturers, mentioning your dealer's name.

DAFFODIL DAYS

February smiled. And lo!—
Down the garden valleys blow
Yellow frills
Of Daffodils;
Fluttering in windy spaces;
Curtsying in sheltered places.
Sunlight shed through naked trees
Has no fairer glow than these
Precious hostages of Spring,
Set with tall leaves in a ring—
Flame-like blades of shining green
Drawn to guard each golden queen.

C. S. MONITOR

MARCH WIND

Rough courier that speaks the swift advance
Of lifting hyacinths and tulip tide;
And warming earth that shows the thin green lance
Of tender grass on meadows rolling wide.
Vanguard of force to clean the drab terrain
Of Winter's crowding flotsam, so that out
The willow trees will drip with silver rain,
Through the wet witchery of an April noon.
We hear it roaring down the country-side,
And through the city as the shutters swing;
A shouting envoy and a bustling guide,
To blaze a pathway for the timid Spring.

C. S. MONITOR.

What can be more delicious than a morning dawning through your open windows, to the sound of innumerable birds, while the shadows of branches and leaves sway to and fro along the wall, or spread new patterns on the floor, wavering with perpetual change? *Reacher.*

Kramer

Work of Davey Tree Surgeons on a

Westbury, L. I., Jan. 15, 1923

THE DAVEY TREE EXPERT CO., INC.,
KENT, OHIO

Gentlemen: During the past few years I have had occasion to come in contact with your representatives, and also to observe considerable of your work. My opinion of the personnel of your organization and the quality of your work is very good.

I had an experience recently, too, that impressed me very favorably with the service of your Company. A short time after I took charge of the A. Ludlow Kramer estate at Westbury, L. I., your representative called to inspect the work on the trees that you had previously treated, and after his inspection informed me that the numbers of fillings which you put in were standing perfectly, with the exception of one filling that showed a slight defect. He is arranging to have this taken care of without any obligation to Mr. Kramer.

This free service came entirely unsolicited by either Mr. Kramer or myself, and proves conclusively to me that your interest in the trees you treat does not end with the payment of the bill.

I can highly recommend you to any one desiring to obtain the services of

Sincerely yours, Wm. McLeod

Every gardener and estate superintendent has a most important work in the saving of trees under his care. Davey Tree Surgery brings to his aid the highest development of science plus a generation of experience. A careful examination of your trees will be made by appointment.

THE DAVEY TREE EXPERT CO., INC., 205 Elm Street, Kent, Ohio

COLDWELL LAWN MOWERS

Five New Assistants

When large areas of lawn need attention, The Coldwell Imperial Gang Mower steps in with the capacity for work equal to five new assistants.

Cutting a swath 91 inches in width, it wins new records for acreage each passing day, little minding the character of the turf, nor its undulations.

Composed of five high wheel Imperial hand machines, this gang mower, as a unit, possesses the same flexible qualities, the same light-draft requirements, that has made the individual Imperial such a valuable piece of lawn-maintenance equipment.

Hyatt Roller Bearings, Reversible Bed Knife, and special ribbed guard rollers to prevent skidding are part of the ensemble. Whether tractor or horse drawn, The Imperial Gang Mower is particularly efficient where large areas of lawn need to be cut, but not rolled.

Things and Thoughts of the Garden

WILLIAM N. CRAIG

THE New York flower show this Spring, in spite of its unusually early date, proved to be an excellent one, the exhibits being well varied and attractive. The gardens were as usual the cynosure of all eyes; they certainly entail a great amount of study as well as forethought and skill. It was really remarkable that so much well grown, finely flowered and tastefully arranged material could be gotten together at so early a date when the nature of the past—or rather present—Winter, the fuel situation, and other factors are considered. The Spanish garden of Julius Roehrs Co. was quite unique, and a most decided breaking away from existing types, the award of the gold medals of the Architectural Club, and the Garden Club of America to this exhibit made it the most discussed and criticised garden in the show.

* * *

I must admit, however, that the garden which appealed to me the most was that of the F. R. Pierson Co. This was eminently practical and quite possible of duplication in the East; the material used was well placed and, better still, the various plants were plainly labelled. The rock garden of Bobbink and Atkins was well conceived and most interesting; here again all plants were named, thus making it educational. The Azalea Garden from the last named firm was very showy and proved that there are still some Azaleas in America. The rockery of the Julius Roehrs Co. was also nicely done. The Bulb Garden of John Scheepers was very charming and the color arrangement expusite. I had hoped to see two or three rose gardens, however, the one from Cromwell Garden could hardly have been improved upon, and the effect produced by using not only half a dozen varieties, was vastly better than if a much larger number had been planted.

* * *

There was an evident tendency to overcrowd the beautiful arrangements of greenhouse flowering plants from Mrs. Payne Whitney, and W. B. Thompson, half the number of plants would have produced a better effect. I was glad to note how popular *Buddleia Asiatica*, introduced about eleven years ago by Farquhars' of Boston, had become. Both florists and professional gardeners are now recognizing its decorative value. *Clarkia* "Salmon Queen," a lovely annual for pot culture as well as the garden, and one possessing splendid lasting qualities as a cut flower, was noted in one group, also well flowered plants of the single annual *Chrysanthemums*.

There was a wonderful array of Orchids. These were, however, fearfully crowded, and one or two of the largest groups were very poorly arranged. The *Cymbidiums* were easily the star features in this department. I think I noticed a name on the beautiful *Brasso-Lælio-Cattleya*, "Snowdon," from A. N. Cooley of Pittsfield, Mass., and it is just possible that one or two others had names, but not a solitary label appeared on the bulk of the groups. This held true throughout the entire exhibition.

* * *

I presume that flower shows are held to satisfy and encourage the love of people for flowers, and particularly to make such exhibitions educational. They utterly fail in this latter most essential particular when so few plants and flowers are named as in New York. Personally I think the policy of the Massachusetts Horticultural Society which insists on all exhibits being named, and the refusal of awards to any plants and flowers not plainly labelled, might very well be adopted in New York. Small inconspicuous cards either printed, or plainly written in ink, should be made mandatory. If this is not done, this greatest of our Spring flower shows will fail in its full mission.

* * *

The cut flower displays at New York are always excellent and this year were fully equal to those of former years. The sweet pea display of W. Atlee Burpee & Co. was as usual a splendid one, being also most artistically arranged, and free from the abominable draperies which disfigured the first and second prize groups of cut roses. My own personal opinion was that the F. R. Pierson Co. display, everything considered, was the best of the three. I may be old-fashioned but I am opposed to giving premiums to lavish displays of ribbons, chiffon, or even colored burlap and tissue paper. Amongst the new roses America, Commonwealth, Mrs. Harding, and *Souv. de Claudius Pernet*, all had their admirers. The last named was the centre of attraction for amateurs, as it is proving to be a good garden rose, and its color reminds one very strongly of that beautiful variety, *Marechal Neil*, by long odds the finest climbing yellow we have today but, unfortunately, too tender for our cold eastern states.

* * *

It is always interesting to note what are commonly classed as "spring flowers." A nice assortment of these appeared, especially amongst the table decorative material. Amongst the forced annuals and bulbs used I noticed

Didiscus cœrulea, pink *Clarkia*, *Gypsophila elegans*, pink *Saponaria*, *Statice Suworowi*, *Leptosyne maritima*, *Arcotus grandis*, blue and white *Lupines*, *Larkspur*, *Nemesia*, *Schizanthus*, *Stocks* single, *Sweet Peas*, and *Centaurea cyanus*, all of which are also excellent outdoors. Bulbous flowers apart from *Narcissi* consisted mainly of Dutch and Spanish *Iris*, *Ranunculus*, *Ixias*, *Sparaxis*, and colored *Freesias*. A vase of *White Watsonias* was noted also a few of the large flowered *Gladioli*, which looked as though they might have been grown in Florida. Since the advent of Quarantine 37 we see comparatively few of the miscellaneous Dutch bulbs such as *Babianas*, *Tritonias*, *Ixias*, *Ranunculus*, *Anemones*, and *Sparaxis*, bulbous *Iris*, and the small flowered *Gladioli* are also comparatively scarce and high priced.

Speaking of *Watsonias*, these lovely South African bulbous plants have been tremendously improved by hybridization of late years in Florida, California, and Australia. E. H. Wilson during his recent world tour found a wonderful race of hybrids in Melbourne, plants growing six feet in height and including about every imaginable color. Splendid hybrids have also been produced in the warmer parts of our own country. I have found that *Watsonias* flower splendidly in pots, and will also succeed quite well outdoors. I think they should do finely in benches, and are well worth careful consideration from commercial growers. In Spring groups of plants they should prove extremely useful, and seeing that a goodly supply of bulbs is available in both Florida and California those who want something new in their gardens might well try them. The colors most in evidence are pure white and peach pink. These have well branched spikes carrying fifty to seventy-five flowers each.

It seems strange that so many amateurs and not a few practical gardeners are still of the opinion that members of the *Primula* family are of doubtful hardiness in our northern Atlantic states. If given conditions at all congenial they are among the most dependable and charming of hardy plants. They will grow and flower well in full sunshine, but are most at home under the shade of trees, (elms excepted). In shady situations the white, yellow, and gold laced *Polyanthus* thrive amazingly as do the English primroses. At the late New York show I was interested to find in one of the gardens *Polyanthus* labelled "English Primroses," and in the same lovely garden "St. Bridget" in lieu of *St. Brigid Anemones*. In addition to the *Polyanthus* and English Primrose there are many other hardy *Primulas*. The following have done especially well in the vicinity of Boston: *P. frondosa* a lovely little sort with silvery foliage and rosy lilac flowers, *P. pulverulenta*, a vigorous sort succeeding particularly well in moist locations where its rich, ruby crimson spikes are very effective; in suitable locations it will reproduce itself from seed very abundantly. *P. Japonica* is a good rock plant, it comes in a wide range of colors, and is very much at home along the margin of ponds or streams. *P. Beesiana* is a strong grower with varying shades of purple flowers and a yellow eye. *P. Bulleyana* produces buff, orange, and apricot colored flowers, very distinct from all other *Primulas* and is the latest bloomer in the whole family. A pretty little dwarf growing variety is *P. rosea floribunda*, flowers are bright rose in color. *P. Sikkimensis* is commonly called the "Himalayan Cowslip" the primrose yellow flowers are produced in clusters on long scapes. *P. Cashmeriana* and *P. denticulata* have always been the first of our *Primulas* to flower, not infrequently as early as the middle of April near Boston. They grow eighteen inches in height and their globe shaped heads of flowers vary in color from pure

white to purple and violet. The foregoing *Primulas* have proven quite hardy, and but few have died out. It is always a good plan to raise seedlings of one or more varieties each Spring and while *Primulas* will withstand very low temperatures, they should be given a mulch of leaves as Winter sets in and it is well not to remove this too hastily in Spring.

Lilacs are unquestionably the finest of all our flowering shrubs. They flower early and abundantly each year; hold their foliage late; are absolutely hardy, and are clean subjects, as with the exception of scale, they are practically immune from insect attacks. The San Jose and other scales are easily controlled by a dormant spray of either lime-sulphur, or one of the several soluble oils. For the wonderful improvement in, and popularity of lilacs, we are indebted to one of the world's greatest horticultural hybridizers, Lemoine of Nancy in France. M. Lemoine's nursery was close to the firing line and was frequently shelled by the Germans, but terribly crippled and hampered as he was, he continued the work of hybridization, only to be met at the close of the world war by that cruel and utterly unjustifiable embargo, the notorious Quarantine 37.

There are two hundred or more varieties of Lilacs in cultivation in America today, the bulk of them raised by Lemoine. We are devoutly grateful that we had them before the F. H. B. started to function. Out of a very long list of hybrid Lilacs I would recommend the following as excellent: *Marie Le Graye*, still the best single white; *Mme. Lemoine*, a superb double white; another lovely double white is *Mme. Casimir Perier*. In the dark purple class *Souvenir de L. Spaeth* is still hard to beat. The most exquisite pink of all is unquestionably *Macrostachya*; another good pink is *Mme. Francisque Morel*. A grand single blue is *President Grevy*; *Michael Buchner* is a good double pale lilac colored variety. *Lucie Baltet* is a fine single, with old rose colored flowers. *Senator Voland* has big trusses of single reddish color. A striking deep red double is *Charles Joly*.

Apart from the named hybrids of *Syringa vulgaris* already listed above, everyone should plant some of the species. *S. Rothomagensis* the Rouen lilac, *S. Persica* and *S. Persica alba*, the graceful purple and white Persian lilacs, the very graceful *S. pubescens* are all valuable; also *S. Josikæa*, the Hungarian lilac, is valuable as a late bloomer. Latest of all comes *S. Japonica*, the Japanese tree lilac of tree-like form with handsome glossy leaves and big plumes of creamy white flowers produced after all other lilacs have passed.

It is most encouraging to learn that an extensive and comprehensive investigation of the methods and activities of the Federal Horticultural Board, including their efficiency and general methods, and the best methods to adopt to effect any necessary changes will be undertaken by the Chamber of Commerce of the United States, if a request addressed to it by the Merchants' Association of New York receives favorable consideration. Several months' study of the autocratic F. H. B. and its methods, by a special committee of nine gentlemen has made possible this most refreshing report. Every true lover of horticulture in its truest and broadest sense will fervently hope that the committee's recommendations may be favorably received, and that the comprehensive study asked for may materialize. I have long thought that if we had only possessed a great Central Chamber of Horticulture, such as Great Britain possesses, the scientific theorists comprising the Federal Horticultural Board would never have dared to attempt to put into force a virtual embargo against practically all plant products.

In the Garden and in the Greenhouse

GEORGE F. STEWART

WITH the advent of this season of the year, late April and early May, the garden will be beginning to be clothed with all its Spring beauty—suggesting many thoughts to the observant mind. I see, in plant-life and action, parables or illustrations of some of the old Bible teachings. After the long Winter sleep we have a resurrection, and then the great truth that it takes death to give life. Dead and decayed vegetation feeding and giving life to the flowers and foliage of the coming season. A verse written by some poet—I do not know who, comes to mind. I do not even know if I quote it correctly, but it has stuck to me for years, after, no doubt, reading it somewhere.

Life evermore is fed by death,
In earth and sea and sky
Before a rose can breathe a breath,
Something must die.

If any of my literary readers know the author, and the poem, if it is a poem, I should like to know more of it and who the poet is.

Everywhere the gardener turns at this season work in many forms confronts him. A cool and calm mind is a great gift to those who possess it. The young gardener who has been fortunate enough to secure the management of an estate may be full of life, energy and enthusiasm, which, if not kept in control, may lead him into deep waters. However, we all make mistakes so let us profit by them.

If there is any belated work on the lawns to be done, let it be pushed to a finish quickly. Grass seed, if sown without delay, will germinate quickly at this season, especially if we get an occasional warm shower. If there comes a dry spell, watering with a fine sprinkler will be necessary on newly seeded lawns. After it is well up a good rolling will help to firm the roots. Careful attention given to a lawn the first season generally determines what it will be in after years. To have it in first-class condition weeding must be resorted to, as no matter how carefully it has been cultivated and made, previous to seeding, there will always be more or less weeds to annoy one.

Cabbages, cauliflowers, and Brussel sprouts that were started early may now be planted out. In the cultivation of these, and all plants of the Brassica family, newly broken up grass land is best to plant them in. They are far less liable to clubroot. They like a deep, rich, well cultivated piece of land to grow in, and plenty of room to develop each plant. Two feet between each plant, and three feet between the rows, is about right, although they may be grown much closer if land is scarce, and one has plenty of time to feed them well with liquid and other manures. We once grew, for experiment, thirty-six nice medium sized heads of cauliflower on a piece of ground six feet by six. They, however, were fed heavy with liquid manure until the heads formed. Firm planting is in order; for these plants also care should be exercised that the roots are well down into the soil.

There is yet time to sow and get a good crop of onions although they are better when planted much earlier. Enrich the land well for this crop and tread and firm the ground before sowing the seed. The leek is one of the healthiest of vegetables. A deep, rich soil is what they require. They are better if trench grown so as to have a better chance to blanch. Dig a trench at least fifteen inches deep and, after it is finished, loosen up and manure

the bottom heavily, and cover with a little loam, as it is safer to plant the young plants in soil not so rich, having the roots gradually reach the more heavily fertilized part.

Peas are probably the greatest favorite of all vegetables and they should get good care so as to secure a good crop. They have been cultivated since before the time of Christ, and are known botanically as (*Pisum sativum*). Peas like a good deep rich soil, but manure that is used for them should be well decayed. One of the best ways to plant peas, as we have found, is to plough out a good deep trench, and manure it well in the bottom, covering the manured part with a few inches of soil that has been manured the previous season. Sow the seeds on top of that, covering them about two inches. As the young plant grows the roots gradually penetrate the manured part as they gain vigor. We have seen sowings spoiled by sowing the seed too near the manure especially if it was not well decayed. Peas also like land that has been well limed or has a mixture of chalk in it. A cool steady climate is best for them, and those who live close to sea shore can have a much longer season of peas than those of us who live further inland.

Get in parsnips as soon as the ground is prepared for them. If one has the time the best way to grow them, after the ground has been prepared, is to use a good thick dibble about three feet long and bore holes in the prepared ground about six to eight inches apart. Fill these holes with fine loam, or sand, and sow a pinch of seed on the top of each hole. After the plants are well started, thin them out to a single plant. This method ensures a good long straight root. At one time parsnips were recommended as a substitute for potatoes, but, of course, that fell flat, as the flavor of the potato is, I believe, more popular than that of the parsnip. Deep rich soil, free from stones, rather sandy in texture is best for them. The modern name is *Pastinaca sativa*; older Botanists placed it under *Peucedanum sativum*.

Stakes may be placed in position for pole beans and by the first of May, a sowing of dwarf beans may risked in a warm sheltered spot outdoors. If a late frost occurs a newspaper placed over the row will, we have found, generally save them. It does not take long to cover them, and if a small stone is placed on each corner of the sheet, there is not much danger of the wind blowing it away. See that the paper does not touch the top of the small plants, as if it does, they are about as certain of being nipped, as if they were uncovered.

A sowing of early corn may also be tried. We have saved the hills from a late frost by covering them with a flower pot. A well enriched hillside, sloping south is the safest to plant early corn on. For flavor it is hard to beat the various forms of Bantam.

Keep up successive sowings of beets, carrots, and lettuce. The main crop of potatoes can be planted any time in May. New land is always advocated for them, but we gave them two years on the same piece of ground a year or two ago, and the second year we doubled the yield. We used a regular commercial potato fertilizer and no barnyard manure.

Fall blooming plants in the herbaceous border can be overhauled at this time if they require it. The plant should be completely dug out of the ground and the space for it manured and limed. Select the best part of the crown to replant—merely cutting around a few pieces off the edges of the crown is not good gardening. There

are a few annuals that are better if sown where they are intended to grow; *Lavatera*, the poppy family, *Alyssum*, etc., any good catalogue will tell one which are sensitive to the roots being disturbed. We have had very good success by filling small pots with soil, sowing a pinch of seed in the middle of each pot and thinning out after they are well up. We place the pots in a cold frame, removing the sash when weather allows. By this method they come along quite naturally, and they can be planted in their flowering position before they get too well rooted.

Get all plants of Foxglove (*Digitalis*), Sweet Williams, and other plants that require the same treatment, into their flowering position without delay.

About the middle of April we always plant our first batch of gladioli. These we find are of the most valuable cut flowers, especially the *Primulinus* hybrids. They are, to my mind, far more decorative than the *gandavensis* type. Cross breeders of this valuable flower, in their eagerness after size, and departure from distinct colors, are in my opinion destroying their artistic effect, when it comes to the arrangement of these flowers. We find that a planting every three weeks up to about July 18 gives a good steady supply of flowers until frost. Small bulbets of the *Primulinus* type, sown in a drill, like seed, flower splendidly all through the Fall. We plant gladiolus bulbs six inches deep. They like a heavy coating of lime in the soil. *Montbretias* are also very fine cut flowers but they are not quite hardy around here. We have found the best way to handle them is in a frame, where they can be protected somewhat in Winter. When they get overcrowded lift them and replant. Botanically they are placed under *Tritoma*.

Antirrhinums that have been well hardened off, can now be planted in their flowering quarters. A little frost does them no harm.

Canterbury Bells (*Campanula medium*) may now be sown for next year, also *Campanula pyramidalis*.

Another batch of late flowering China Asters may also be sown at this time. Sow them on top of sphagnum moss, pressing the seeds into it and in this way, we find they germinate much more freely. We would again draw attention to the single asters. "Southcote Beauty" is preferred by many, especially those that have had their artistic sense trained, to the large double flowered type. We question sometimes if much of our cross breeding after large double flowers is progressive, or retrogressive.

To many, now that the Spring flower show season and Easter is past, the grand climax, so to speak, of the plant end of greenhouse work has passed, and from now on visions of what we have in mind for the next season will be rising before us. Here again the value of keeping daily notes will be proved, as comparison can be made of how early or how late certain plants flowered. Forcing with extra heat, to get a given plant in flower for a certain date, we have always found bad for the lasting quality of the flowers, and the constitution of the plant is very often weakened. We have always found it better to retard the flowering period, after the flowers show signs of opening in a lower temperature with a light shade over the plant. It is very disheartening to a conscientious judge at a flower show, to see a plant, or vase of flowers, go to pieces soon after a decision has been made, causing thereby much ill feeling on the part of other exhibitors in the same class.

Pot all late March and early April flowered hardwood plants as soon as the tips of the shoots show signs of starting into growth. As I said in last year's notes, I have proved to my own satisfaction, that pruning the plants into shape is better if done just after the newly potted plants are commencing to grip the new compost. Never give a large shift to this class of plants. I saw

a batch of *Azalias* quite recently, where the receptacle was about as much in diameter as the plants. Such a condition I have never heard recommended as good culture. Personally I can never avoid looking at the pots, no matter how well flowered the plants are. There is a fine old veteran plantsman I know, who every second year takes its hard wood plants out of their pots and plants them out all Summer in a specially prepared bed. I asked him once how he managed to keep them in bounds at the roots. He told me that the peat bed in which he planted them was very friable and sandy, and he just gave them a good shaking and there was nothing left but the roots. They were very large plants and he had kept them in the same size tubs for many years. After potting, he kept them a little close for a week or ten days and then transferred them to a cool pit until they were wanted to flower at various periods during the late Spring.

In the rush of Spring work, do not forget to spread out and work over the soil that is intended for benching carnations and roses later on. The carnation requires a much lighter soil than the rose, and in mixing each batch, keep this in mind, also that the former resents the use of green manure. It should be well decayed before the plants are planted in it. The rose in our experience is not so sensitive to the use of fresh material from the cow barn, even when a good dressing of bone meal is used along with it. Expose the soil for each of them to the air and sunshine, as it absorbs more plant food from the atmosphere, beneficial to the plants, which is not so easy to add artificially. Deep wide compost heaps in my opinion is not the best method of storing soil, the middle of them is too likely to get into a dead inert condition, owing to not being exposed to air and sunshine.

Calceolarias will by the end of April need to be thought of, that is, if large specimens are the object in view for next year. The herbaceous type always comes through the hot months better, if nice sturdy small plants are established in 3½ in. pots by the first of July. These early sown plants quite often in the early Fall will set flower buds, but if they are pinched off, about a week after they receive a potting, will break quite freely and can be moved along until a twelve-inch pot is reached before they cease growing. Under this treatment if they receive a compost, such as we advised in last year's notes, with the usual conditions under which *calceolarias* are grown, plants three feet in diameter can be had in about one year from seed. Nearly all seed houses of reputation have good strains of the herbaceous *calceolaria*.

The shrubby type which we see quite commonly around the East, are best grown into large specimens from cuttings rooted in April. They will flower as small plants in June, which will do them no harm. These if kept in a shady position and only watered when they show signs of wilting during the hot months, even if they do not look very promising by the middle of September, can then be potted along from the small pots. They will break all over the shrubby stems and these breaks can be pinched several times during the Winter a few days after they receive a shift, until from six to eight weeks before they are wanted to flower; eight weeks early in the year, reducing to six as the Spring advances. These notes are written for those who desire large plants of both kinds of *calceolarias*. Small plants of both types for mass decoration may be sown and rooted very much later in the season.

Chrysanthemum lovers are now watching their young stock with care, moving them along until their flowering pots are reached. Although they enjoy plenty of plant food, it can be very easily overdone in the early stages of growth. Bench grown stock on the average private

estate, is not so useful as that grown in pots. These can only be used as cut flowers, whereas the pot plants, grown to a single flower, may be used in a greater variety of ways when it comes to grouping plants, and very often after they have done duty in a decoration they are still there to use for vase work. The bush plants are now laying the foundation which determines their future size and shape. Pinch them as evenly as possible which will make it all the easier when the time arrives for their final training.

Young carnation plants that are to be grown in pots until the benches are available, may now be placed in a cold frame. Lift off the sash when weather permits, and pinch them as soon as there is any indication of a flower bud. A clean cut through the stem is better than breaking with the fingers. Field grown plants may be planted out by the first of May if weather is at all normal, and they have been grown cool and sturdy. I personally do not favor field grown plants for a private estate.

Young roses will have been secured by this date. They ought to have a good position, and the best of care that it is possible to give them.

The Fall sown cyclamen plants, to obtain such plants as I saw at the New York show, need all the love and cultural skill which that popular plant has brought forth in recent years, bestowed upon them. A special article by those excellent growers in *THE CHRONICLE* would be very profitable to us all, provided every detail were given.

Early gloxinias will now be better to have a little assistance towards flower production. Stimulate them to that end by applications of cow manure water and soft coal soot. Keep it away from the foliage which is easily disfigured by water in any form. However, until gloxinias expand their flowers, abundance of moisture is necessary in the compartment they are grown in, to bring out their full development. In the tropical house, as much space as can be allowed for each plant from now on, should be the aim of the grower. Later on when plants are set outdoors, another house may be utilized for these plants. Overcrowding mars the beauty of their foliage. Floors, and the benches between the pots should be sprinkled several times a day, and when the weather gets tropical outdoors abundance of air given.

Don't forget to have the Primulas and Cinerarias sown by the end of April. A later sowing of Cinerarias may be necessary, also of *Primula malacoides*. The plants of this *Primula* at the New York show were the finest for culture which I have seen equaled only once, and the strain at that time was very inferior to the New York plants.

Orchids should not be coddled in too warm quarters after this season of the year. They all delight in plenty of pure air, even the most tropical, and advantage should be taken of the weather outdoors, when it is most favorable, to see that the structures they are grown in have the atmosphere conditions suitable to the different genera. From my experience with orchids, they all, in their growing season, delight in plenty of moisture, especially in the atmosphere, watering at the roots should be thoroughly done when any is applied, and before any more is given, they may be allowed to be a little on the dry side. Sometimes it is a little deceiving for the compost may look dry on top, but if examined a little below the surface, will be found to be quite moist. Watering is learned by experience and almost becomes an instinct.

The fruit houses are at various stages of development. The very early forced fruits, such as grapes, peaches and nectarines, are ripening with some, no doubt. Syringing must stop until the fruit is harvested, use judgment about the condition of moisture in the borders, rather on the dry side as the time approaches for gathering, and have

plenty of top and bottom air when the weather is at all favorable. A little extra fire heat, if a raw biting day prevents airing, as one can do on a warm Spring day may counteract to some degree the conditions outdoors.

Let the late fruit houses come along naturally without any forcing. Rub off all extra buds on the spurs as soon as the strongest can be seen. Be in no hurry about tying down the shoots. If there is plenty of head room above the wires which every grape house ought to have, let the weight of the bunch do that work, and there will be no loss of shoots by snapping, which is often caused by premature tying into the supposed position.

We have had a very trying Winter, in which many of our calculations and theories have been somewhat upset. Let us be certain to profit by it.

NEWCOMERS IN OLD GARDENS

ALTHOUGH the Blue Lace Flower has been catalogued sparingly for several years, it is still a novelty and is seen in only a few gardens as yet. There have been misconceptions about this annual. It has been spoken of, for example, as a form of Queen Anne's Lace, which grows wild in the fields, but in truth is an entirely different plant, coming from Australia, and bearing the name of *Didiscus cœrulea*, writes E. I. Farrington in *The Christian Science Monitor*. Moreover, it has been known to botanists for many years, but did not win favor with gardeners until introduced by a New York florist, who surrounded it with a mild mystery at first and thus excited public interest. Old as it is, therefore, it is yet a novelty and an attractive flower, which is especially good for cutting. The amateur should remember, however, that the seeds are rather slow to germinate. Starting them in boxes in the house in April is the best plan, although, if given careful attention, they can be sown in seed beds outside when danger of frost is over. Barely cover the seeds with soil and give them two weeks to sprout.

The old-fashioned sunflowers are not usually represented in the intimate garden, but there are several small-flowered, refined species and varieties which are well worth a place in the hardy border. A newcomer in this class is called Autumn Glory, and deserves its name, flowering as it does very late in the season and presenting great masses of golden-yellow blooms that suggest giant daisies. The plants grow four or five feet high, and although perennials, coming up year after year, they will bloom the first year if seed is sown early.

Egypt contributes a novelty this year in *Dimorphotheca eklonis*, evidently a species of the South African daisy which has been grown for several years and is a good garden annual. The new flower is a dwarf, growing scarcely more than 15 inches high and the blooms are star-shaped, fairly large and white with a deep-blue disk. It has yet to prove its merits, but seems likely to grow as well as its cousin.

For years zinnias were looked upon as plebeian, but within the last two or three seasons have been raised to a much higher estate. Now the most fastidious garden makers are growing them. The reason lies in the development of flowers in new and most delightful shades, particularly soft pastels, which make them unsurpassed for house decoration.

There are many new and probably improved varieties of the old-time favorite garden flowers, some of which are worth experimenting with. This is especially true in respect to snapdragons and larkspurs, both of which are such delightful garden subjects that any new offerings among them cannot well be overlooked, even by cautious garden makers who are prone to view all novelties with suspicion.

The Tenth International Flower Show

FLORUM AMATOR

FROM the very moment a visitor to this show, held in the Grand Central Palace, New York City, March 12 to 17, 1923, reached the head of the broad stairway leading to the main floor, he was caught and held by a loveliness of color, a beauty of form, and an intoxicating perfume, a combination found only in the republic of flowers. Garden on garden of flowering and foliage plants, in charming arrangements and groups, and single specimens, and vases of beautiful cut flowers confronted him and hemmed him in on every hand. When later he passed from the main floor scene of beauty to the mezzanine, he found a supplement of that on which his eyes had just been feasting.

ond prize, was not far behind in the number of plants used. It is, it seems to me, vain to waste words in saying by way of criticism that such gardens as these with their great wealth of blooms, appearing on a large variety of plants at a time, are impossible in real gardening in the open, even in the most favorable season of the year, and in the most congenial part of our country climatically. True it is, that not a garden exhibited at this show, either by private or commercial growers, could be produced and maintained for a week under the open sky. Such gardens, however, as these, are justified by the fact that only by the setting up of high ideals is advancement gradually gained and potentialities made realities. The main fea-

The prize-winning group of flowering plants exhibited at the International Flower Show by William Boyce Thompson (Andrew Strachan, gardener) arranged as a garden

During several days of the week in which this greatest of all flower shows in this country was staged, the elements were unkind and doubtless curtailed somewhat the aggregate attendance. The 1923 New York Spring Flower Show, nevertheless, as regards the number, variety, and quality of its exhibits scored a distinct success.

Without the many admirable gardens, groups, and single specimen plants, staged by the skilled gardeners of private estates, this Tenth International Flower Show would have been like "Hamlet with Hamlet left out." On the main floor directly in front of the head of the stairway leading thereto and attracting at once the attention of visitors, were two groups arranged as gardens, each covering five hundred square feet, of flowering plants. Both were lavishly planted with hardy and tender flowering stock: that of the first prize winner, William Boyce Thompson, Yonkers, N. Y. (gardener, Andrew Strachan), the more so, but that of Mrs. Payne Whitney, Manhasset, L. I. (gardener, George Ferguson), which drew the sec-

ures of Mr. Thompson's garden were a central bed of *Primula Kewensis* with an edging of *Sweet Alyssum* and four other beds of *Primula malacoides*. In the background were tall *Clarkias*; a pergola covered with *Dorothy Perkins* roses; *Acacias*, *Genistas*, and *Chorizemas*. The pillars at the front corners were wreathed with *Excelsa* roses and on each side of the front and two side gates were *Dorothy Perkins* roses and lilacs. I liked the three gate features of this garden, warm invitations, as it were, to enter its precincts. Mrs. Whitney's garden, however, was a very close second to Mr. Thompson's, the chief features of which were a center of green sward interspersed with stepping stones; little groups of crocuses growing in the grass; on each side of the gate double *Van Sion* narcissus, tulip *Clusiana*, snapdragons, and *Lilium rubrum*; *Buddleia Asiatica* around the front corner pillars and *Darwin* tulips at their sides and back; a background of rhododendrons, *Genistas*, lilacs and hardy azaleas against a higher background of late cedars.

One of the most handsome exhibits, it seemed to me, in the entire show, though far from the largest, was the William Boyce Thompson group of foliage plants. Mr. Strachan's skill as a grower and a garden architect was even better manifested in this than in the flower garden. Crotons, wonderfully well colored, banked on three sides were the main features but scarcely less beautiful were the fancy-leaved Caladiums, Pandanus, and Dracenas within the embankments of Crotons and amidst a setting of *Adiantum cuneatum*. Plants of *Phalaenopsis* gave a floral touch and light to this elegant group.

The splendid cyclamen plants, seventy-four in all, exhibited by Mrs. I. A. Constable, Manaroneck, N. Y. (gardener, James Stuart), and by Mrs. Daniel Guggenheim, Port Washington, L. I. (gardener, Thomas Leyden), and felicitously arranged to form one great group throughout the week of the show appeared to claim from visitors scarcely less well deserved attention than the gardens.

Orchids with the wondrous beauty of colors and strange forms of their flowers always enthrall a crowd of visitors. Especially notable was the group of twelve plants of Col. H. H. Rogers, Tuxedo Park, N. Y. (gardener, Pasquale Venezia), made up of *Cymbidiums*, *Phalaenopsis*, *Cattleyas*, and *Brasso-Cattleyas*, shown amidst a setting of *Adiantum* ferns, and six plants of the same exhibitor comprising *Oncidiums*, *Cymbidiums*, *Cattleyas*, and *Phalaenopsis* arranged with greens, and again by the same exhibitor the specimen plant of *Lælio-Cattleya*, *Mabel*, and the *Brasso-Cattleya*, *Maronii*. Equally fine in the open class was the group covering one hundred square feet of James B. Duke, Somerville, N. J. (gardener, A. E. Miles), in tier arrangement, the leading features of which were *Oncidiums* and *Cymbidiums*, and the specimen of *Brasso-Cattleya*, *Fournerii*, the winner of a special

silver medal. Very interesting also was the prize winning group of twenty-five hybrids of the same exhibitor. The newest orchid, perhaps, in the entire show was the splen-

did *Brasso-Lælio-Cattleya*, *Snowden*, with its white flowers of enormous size, shown by William Arthur Cooley of Pittsfield, Mass. (gardener, Oliver Lines), and the

winner of a gold medal. The immense *Cymbidium*, exhibited by Mrs. Bertram H. Borden, Rumson, N. J. (superintendent, William Turner), bearing nearly four score flowers, was a wonderful specimen.

The twelve broad-leaved and the twelve narrow leaved *Crotons* of Miss Alice De Lamar, Glen Cove, L. I. (gardener, James McManus), and of Mrs. Daniel Guggenheim, each exhibiting both types, outside of the William Boyce group, seemed to me to be the most noteworthy display of foliage plants in the show.

Cineraria hybrida plants shown by Mrs. B. G. Work of Oyster Bay, L. I. (gardener, Robert Honeyman), and by Samuel Untermeyer (gardener, A. A. Leach), represented well the older type of this plant, and an equal number shown by William Boyce Thompson and C. E. Mitchell, Tuxedo Park (gardener, James Ventola), of *Cineraria stellata*, defended successfully the modern type of this plant.

Excellent indeed was the silver medal winning group of *Acacias* with an intermingling of *Imantophyllums* (*Clivias*) of Mrs. F. A. Constable, and the certificate winning specimen of a lighter colored specimen plant of *Imantophyllum*.

Azaleas in these days of no more importations can hardly as yet be expected to be equal to those of former years, but the group of three exhibited by Mrs. E. F. Luckenback, Port Washington, L. I. (gardener, Thomas Twigg), and by James H. Macdonald, Flushing, L. I. (gardener, Richard Hughes), were good representatives of the old time favorite.

The three *Buddleias*, Asiatic type, shown by Mrs. Daniel Guggenheim, and the three by Mrs. B. G. Work, were very large, fine plants, well foliaged and in full flower, and seemed deserving of a more conspicuous position than they had.

Twelve notably fine plants of *Amaryllis* were exhibited by Mrs. Daniel Guggenheim and twelve good plants of the same by Mrs. F. A. Constable. Six good plants by Mrs. E. F. Luckenback and a like number by Mrs. F. A. Constable filled out well the exhibit of this stately flower.

The most notable exhibit of plants, outside of lilies, whose flowers have an agreeable fragrance as well as beauty of color and form, was that of the twenty-four stocks staged by Mrs. John T. Pratt (superintendent, John W. Everett).

Three *Schizanthus* in a group and one specimen plant, all of giant size and excellence, were shown by William Boyce Thompson.

The *Primula malacoides*, twelve plants shown by Mrs. E. F. Luckenbach, and the same number by J. W. Harriman, Glen Cove, L. I. (superintendent, William G. Carter); the twelve *Primula obconica grandiflora* by Mrs. Payne Whitney, and the six plants in variety by the same exhibitor and by Col. H. H. Rogers, made up a showing of *Primulas* which drew hardly less deserved attention by their beauty and splendid keeping quality than the *Cyclamen* group. And besides these there was a dozen fine plants of the now less often seen *Primula Sinensis*, staged by Mrs. Eugene Meyer, Jr., Mt. Kisco, N. Y. (gardener, Charles Ruthven).

Six plants of *Nemesia*, excellent representatives of this plant, which is little seen in the show room, were exhibited by Mrs. E. Iselin, New Rochelle, N. Y. (gardener, Duncan McIntyre), and also by Mrs. F. A. Constable. Unfortunately this plant does not retain its beauty long in the show room, but we observed among the six plants of Mrs. Iselin two with orange-yellow blooms which seemed to be an exception to this statement.

Especially excellent in the single specimen plants, not previously mentioned in connection with groups, were a *Kentia Belmoreana* shown by Mrs. F. A. Constable; a

Marguerite by Mrs. E. F. Luckenback, and *Asparagus Sprengeri* by Miss Alice De Lamar; a *Cibotium Schiedeii* by Mrs. Daniel Guggenheim, and one by Samuel Untermeyer; an *Adiantum Farleyense* by Mrs. McK. Twombly, Convent, N. J. (gardener, Robert Tyson); a *Cytisus* by Mrs. John T. Pratt; a standard *Fuchsia* by Mrs. F. A. Constable and an *Areca lutescens* by the same exhibitor; two Bay trees by Mrs. E. F. Luckenback and a *Chorizema* by Gen. Howard S. Borden, Rumson, N. J. (superintendent, Percy Hicks); geraniums in bush and standard form and heliotrope in standard form by Miss Alice De Lamar.

The exhibits of bulbous plants were comprehensive and large in the aggregate. Hyacinths staged in good form soon deteriorated. Tulips, especially Darwins, and the splendid group of single early tulip, Gen. De Wet, kept better than the hyacinths and so also the narcissi and freesias. To Mrs. Bertram H. Borden, who staged prize winning exhibits in almost or quite all the bulbous classes, and to Mrs. Daniel Guggenheim were awarded the Scheepers' Gold Medals for achievement in bulb culture. Other exhibitors of well grown bulbous stock were: Mrs. Payne Whitney with Darwin tulips, valley, and hyacinths; James Macdonald showing a collection of hyacinths; Mrs. John T. Pratt with well grown valley and colored freesia; Mrs. Harold I. Pratt, Glen Cove, L. I. (superintendent, Frank C. Johnson), with colored freesia and valley; Mrs. George Dearborn, Rye, N. Y. (gardener, James Tough), showing twelve pots of splendid lilies; Mrs. Harold I. Pratt showing in the open class lilies, covering fifty square feet, arranged with *Nephrolepis* ferns, flowers of excellent quality including *Lilium Harrisii*, *L. Henryi*, and *L. rubrum*. James Macdonald, Mrs. Harold I. Pratt, and Mrs. Daniel Guggenheim carried away the prizes for a collection of hyacinths, for the Darwin tulip, Louise de Valliere, and for a collection of a new race of tulips between Darwin and Early; and the same exhibitors and Mrs. Bertram H. Borden took the prizes for double Early and Darwin tulips, and large trumpet daffodils.

The most noteworthy of the cut flower displays in roses were the Premier of Mrs. H. McK. Twombly; the Columbia of Mrs. F. A. Constable and also of Mrs. E. E. Smathers, Port Chester, N. Y. (gardener, W. D. Robertson); the Ophelia of Mrs. Twombly; a red variety of Mrs. L. P. Child, New Canaan, Conn. (gardener, M. J. Quirk); a yellow variety of Mrs. Insley Blair, and the vases of mixed varieties of Mrs. Twombly and Mrs. Childs.

In carnations, the Laddie and Matchless of Mrs. Insley Blair; the light pink of Mrs. E. E. Smathers and of Mrs. Arnold Schlaet, Naugatuck, Conn. (gardener, E. Lawrence); the Maine Sunshine of Mrs. F. E. Lewis, Ridgefield, Conn. (superintendent, J. W. Smith); and the vase of one hundred fifty blooms consisting of Laddie, Maine Sunshine, and Matchless of the same exhibitor; an unnamed red of Mrs. Blair; the Pocahontas of Mrs. R. Mallory, Port Chester, N. Y. (gardener, William Smith); the immense blooms of a variegated white of George Grant Mason, Tuxedo Park, N. Y. (gardener, D. McGregor); and a variegated white of George F. F. Baker, Tuxedo Park, N. Y. (gardener, William Elling); the red and yellow of Mrs. L. L. Dunham, Madison, N. J. (gardener, Ernest Wild); the crimson of Mrs. S. D. Bliss, New Canaan, Conn. (gardener, John Barry); the Laddie of Mrs. F. A. Constable, and a vase of one hundred fifty blooms shown by Mrs. Payne Whitney, made in this class a remarkably creditable showing.

In sweet peas the displays, each covering twenty-five square feet, by Mrs. William R. Cross, Morristown, N. J. (gardener, A. E. Sailer), and by Mrs. F. E. Lewis; the collection of six varieties, twenty-five sprays of each, of

The attractive exhibit of sweet peas of the W. Atlee Burpee Company, which included many of their novelties, their latest novelty, King Tut, being prominently featured

Mrs. F. E. Lewis and of Mrs. Stuyvesant Fish, Garrison, N. Y.; the one hundred sprays of one or more varieties, arranged for effect, of Mrs. F. E. Lewis and of Mrs. S. H. Gillespie, Morristown, N. J., were justly admired.

In the miscellaneous cut flowers, the splendid lilies shown by Mrs. B. G. Work; the fine stock of Mrs. John A. Topping, Greenwich, Conn. (gardener, George Hewitt); the snapdragons of Mrs. Percy Chubb, Glen Cove, L. I. (gardener, Peter Smith); the Acacia of Mrs. B. G. Work; the white freesia of Mrs. Ridley Watts, Morristown, N. J. (gardener, Samuel Golding); the excellent yellow callas of Mrs. E. F. Luckenbach, and the splendid white callas of Charles W. McAlpin, Morristown, N. J. (gardener, William Brown); the Cypripediums of Mrs. Harold I. Pratt; the Wallflowers shown by Mrs. Henry R. Mallory, Port Chester, N. Y. (gardener, H. F. Bulpitt); tulips by Mrs. B. H. Borden and by Mrs. Harold I. Pratt; splendid mignonette by Mrs. Percy Chubb; lilacs, twelve sprays, by Mrs. B. H. Borden and Mrs. Harold I. Pratt, made up a diversified and interesting exhibit in this class.

On Wednesday, when roses were used in the dinner table decorations, there were six tables, each set for eight persons. All were tastefully decorated, but the three winners were Mrs. H. McK. Twombly, using Ophelias; Mrs. Percy Chubb, using Madame Butterfly; and Mrs. Edwin Holbrook, Stamford, Conn. (gardener, Jack Willis), using Sunburst.

On Thursday, carnations were used, and the competition was very close. The winners were Mrs. Nathan Straus, Mamaroneck, N. Y. (gardener, Thomas Aitchison); Mrs. H. McK. Twombly, and Mrs. Payne Whitney.

On Friday six tables were decorated, sweet peas being the flower used. The decorations all were unusually good, but the prizes were awarded to Mrs. Ridley Watts; Mrs. H. McK. Twombly, and Mrs. Payne Whitney on close decisions.

The decorations on Saturday, when miscellaneous flowers were allowed, called for, and found much artistic ability displayed, both as to color harmony and arrangement. The decisions between the six tables were close, but the awards went to Mrs. John Topping, using Delphiniums, Acacias, and Iris; Mrs. Nathan Straus, using Acacias, Nemesia, and Streptosolen; Mrs. Ridley Watts, using larkspurs, Calendulas, poppies, tulips, pansies, ranunculus, and montbretias.

THE GARDEN CLUB OF AMERICA

THIS club made interesting and unique exhibits in several classes. These embraced: "Artistic arrangements of flowers suitable for a living room, two by three feet, allowed by each exhibit." There were many exhibits in this class, the pronounced feature of which was extreme simplicity. These exhibits which were in class I in their divisions, A, G and C, were maintained throughout the week. Those under A covered Monday and Tuesday, pottery and china containers

being used in which flowers, foliage, berries, shrubs and grasses were allowed; those under B covered Wednesday and Thursday, glass containers, flowers and foliage allowed; and those under C covered Friday and Saturday, metal containers, flowers and foliage allowed.

In Class II Miniature Gardens of exhibitors' original plans, built on a tray two by three feet, were shown and maintained throughout the show. Many very clever plans were exhibited.

In Class III which called for "Suburban Plantings", a house and garage being placed on an interior lot with a frontage seventy-five feet and a depth of one hundred fifty feet, ground practically and attractively planted; model on tray twenty by forty inches. There were an extremely large number of contestants whose very clever exhibits attracted throughout the week a very large number of visitors at the Show and elicited much commendation.

In Class IV Luncheon Table Decorations were shown in two divisions, A and B. In both divisions, A, from Monday till Thursday; B, from Thursday through Saturday, five-foot tables set only with four plates, were used; flowers, foliage and fruit allowed. A combination of simple beauty and of rigid economy was the desideratum in these table decorations, and this was strictly observed in all the large number of exhibits which drew deserved attention by their merits.

THE COMMERCIAL EXHIBIT

IT is well that the wise managers of the New York Spring Flower Show have arranged so that the partial recompense to the builders and exhibitors of gardens for their large expenditures of labor, plants, et cetera, and for their craft spirit manifested pro bono publico, is no longer dependent upon awards of money prizes, which perforce always left some of the exhibitors without recognition. What comparison, indeed, as a basis of an award could there possibly be between that wondrously conceived and constructed Dutch Bulb garden of John Scheepers, Inc. (illustrated on our front cover), beautiful in the chaste simplicity of its array of Darwin tulips and other bulbous flowers, and lovely with its surrounding border of Spring flowering shrubs and trees, and its ivy festooned arches, and the Bobbink and Atkins garden of azaleas with their vivid colors, a perfect gem, reminding one emphatically of those palmy days when Belgium's plants were not shut out of the United States, and at the same time demonstrating what our American plant growers can produce.

Again who could be so audacious as to decide which was the better, the garden of A. N. Pierson, Inc., a rose garden, pure and simple, with low growing rose bushes all abloom, a perfect example of the rose used in under-the-open-sky gardens, a lovely garden to linger in and drink in the sweet odor of roses, and the Oriental court of Julius Roehrs Company, a splendid example of the use of exotic plants in open court architecture, an inviting

place in which to rest under the shade of great palms.

Another garden of the Julius Roehrs Company was a rock garden, paved in part with "Metowee" stones. In the background was a rock wall with a pool at its base, up to which led stone steps, and overspread with conifers. On the one hand there were dogwoods amid greenery, and on the other, a great variety of flowering shrubs, such as are at home among rocks.

Not far away from this, there was the larger and more elaborate, and quite different rock garden of Bobbink and Atkins. This had beds of flowering plants in its wide front of green sward. In the background, there was a mass of precipitous rocks, amidst which plants nestled. Rocky steps led up to this rocky hill, on each side of which were flowering plants. Out of the rock mass there broke a stream which turned an old-time wooden over-shot water wheel.

Passing from these two fascinating rock gardens, I found another garden differing greatly from any which I had already observed, the garden of F. R. Pierson, which fairly commanded attention. In this, two pools, a rockery, and borders of flowering shrubs made up the foreground; Dogwoods, evergreens, and forsythias formed the background. A tall silver birch towered high above the upper pool. In this garden, representing stupendous manual labor as well as brain power, were many blooming shrubs, namely Pyrus, rhododendrons, azaleas, wistarias, spireas, and bulbous plants also. How can anyone think of such a thing as comparing this with the rock gardens; this represents one type, the rock gardens another.

All of the 1923 Flower Show gardens were evidently built by men who had a vision at the very outset of how their gardens would appear when completed. They were not gardens of the patch-added-to-patch kind till the allotted space is filled.

The orchids were also high spots in the show. Notable among the groups shown was the banked display of Julius Roehrs Company; the table display of Joseph Manda Company, and also of Lager and Hurrell, and a group exhibited by George E. Baldwin. All these, staged close to one another on the main floor, made a big beauty spot which was thronged with visitors throughout the show.

Very noteworthy was the border display and the group display of well grown azaleas by Bobbink and Atkins; the Genistas and the Marguerites of Madsen and Christensen; the fine lilacs of Bobbink and Atkins; the magnificent group of Néphrolepis ferns in variety of F. R. Pierson; and last and especially excellent was the two hundred square foot display of a great variety of remarkably well grown Easter plants, staged on a bed of moss by A. L. Miller, Jamaica, L. I. As an example of pot plants grown for purely commercial purposes, there was nothing in the entire show which could be compared with it.

The only commercial display of sweet peas was that covering one hundred square feet made by W. Atlee Burpee Co., Philadelphia, an excellent exhibit of Burpee's fine novelties.

Stump & Walter Company staged a very attractive trade exhibit, various varieties of bulbous stock in bloom, tulips including Gen. De Wet and Ibis; the finest of cottage and Darwin types among which was to be seen the new black Darwin, Mystery, narcissi, hyacinths, lilies, and lilies of the valley. All were arranged to present a very attractive effect.

Charles H. Totty Company also had an artistically arranged trade exhibit, showing cut roses, including Souvenir de Claudius Pernet, Golden Ophelia, Ophelia, Madame Butterfly, Columbia, Annie Laurie. The new rose, Amer-

ica, which was awarded a gold medal, was the feature attraction.

BOSTON SPRING FLOWER SHOW

ADMISSION to the Spring Show in Boston was free this year and the attendance beat all previous Spring show records. Thomas Roland's wonderful acacia garden which filled the lecture hall received a gold medal. There were two hundred plants in tubs, thirty-five varieties, beautifully arranged and all showing matchless culture. It was generally agreed that no such acacia display had ever presumably been made in America. Albert C. Burrage (Fred Pocock, supt.) constructed a large pergola and hundreds of Phalænopsis and other rare orchids were suspended from the same. At the base, for a length of fifty feet, rock work was constructed and orchids arranged in groups were artistically displayed. All pots were covered with green sheet moss and varieties were plainly labelled. There was a wealth of Cymbidiums, Odontoglossums, Odonioidas, Miltonias, Masdevallias, Brasso-cattlevas, and other varieties, awarded a gold medal. A bank of mountain laurel in tubs with a background of hemlocks was attractively arranged by Mrs. Alice C. Burrage, which covered one thousand square feet.

Julius Roehrs Company received a gold medal for the best commercial group of orchids. They also received a first-class certificate for the brilliant Bougainvillea Carmine. A. N. Cooley, Pittsfield, Mass., had a very choice group of orchids and received two gold medals for twelve plants and six plants. Another gold medal went to the Walter Hunnewell estate (T. D. Hatfield, supt.) for the best group of orchids grown on a private estate, which contained some wonderful Cymbidiums. Thomas E. Proctor, Topsfield, Mass., showed a marvelous group of Pink Pearl rhododendrons, smothered with flowers. James Marlborough is an expert grower of these and many other plants. Very fine was the prize winning amaryllis grown by Peter Arnott, superintendent to E. S. Webster.

A noteworthy display was made by Harry S. Rand of Cambridge, comprising over one hundred varieties of Zonale pelargoniums. Schizanthus from Peter Arnott and William Thatcher were very fine, as were also the Cineraria stellata shown by Irving H. Stewart, head gardener to Howard Coonley, Readville, Mass. A large group of cacti from Wollrath and Sons attracted much attention.

Some fourteen of the best models shown by the Garden Club of America at the late New York Show were on exhibition and crowds of visitors were interested in them. They were awarded a gold medal.

On April 5, Herbert Gleason gave an illustrated lecture on Native Plants; on April 6 E. H. Wilson lectured on acacias; and on April 7 Robert Cameron on Spring bulbous plants. The three lecturers addressed large audiences. So great was the interest taken in the acacia display that it was decided to continue it until April 11, which permitted many thousands more to enjoy it.

All that we have willed, or hoped, or dreamed of good,
shall exist,

Not its semblance, but itself; no beauty, nor good, nor
power,

Whose voice has gone forth, but each survives for the
melodist,

When eternity confirms the conception of the hour.

The high that proved too high, the heroic for earth too
hard,

The passion that left the ground to lose itself in the sky,
Are music sent up to God by the lover and the bard;

Enough that he heard it once; we shall hear it by and by.

—Robert Browning.

Strawberries and Their Culture

E. S. HUSSY

STRAWBERRIES require a rich moist and fairly heavy loam. Anything approaching a light gravelly shallow soil is useless; but where such exists it may be improved by a good digging or trenching, at the same time adding plenty of well rotted manure or leaf soil. The end of July to the middle of August is about the best time for planting out strawberries because they get a good start and become well rooted before any hard weather sets in.

The commonest way of multiplying strawberry plants is by means of "runners." These runners are usually produced freely in early Summer. In selecting the runners to obtain good results, the runners must be taken from one year old plants, as they are strong and make an early vigorous growth. They may be pegged down or layered to the ground, or into three-inch pots filled with soil. The latter is on the whole the better method, as the young plants when well rooted are more easily detached from the parent plant and removed to the soil in which they are to be planted. It is an excellent plan to have no more than three or four runners on each plant, cutting all the rest away. The runners must never be allowed to get dry, a little watering now and again will help them. When they are well rooted they may be cut away from the parent plant and placed close together until the time comes for planting.

Having the runners well rooted and the ground properly prepared the plants can be planted in rows two feet apart and eighteen inches from plant to plant. Care must be taken not to plant too deeply as the crown or center of the plant must not be in any way covered with the soil. After planting the soil should be firmly trodden around each plant as strawberries like good hard ground. Neglect of this precaution often results in failure or bad crops. A young plantation should be made every year, so as to keep up the supply of good young plants. Two or three year old plants produce the best and heaviest crops after which they should be thrown away. Therefore it is most essential that a young planting should be made every year. Except when new plants are required all runners should be cut off as soon as they appear, as they weaken the main plant. The soil near the strawberries should never be dug as the roots would be much injured by the process, for they like good firm ground. When growth starts in the Spring a dressing of Nitrate of Soda on a wet day will help them throughout their season.

STRAWBERRIES IN POTS

TO have good strawberries in-doors the first thing to do is to select good strong runners from varieties that are suitable for forcing. They should be layered into three-inch pots filled firmly with rich loam as soon as they can be handled. Having obtained new strong well rooted plants, as described above, they should be potted into five or six-inch pots using rich fibrous loam with a little well rotted manure and a little wood ashes. The pots must be well drained by means of cinders or broken pots. Be sure and pot firmly. Afterward give them a good soaking of water and place them in a shady spot for a few days until they recover from their disturbance. But afterward they cannot have too much sun and air to develop and ripen their growth. The greatest attention must be given to watering, taking care that the plants never become dry or the young roots will become shrivelled up.

On the approach of cold frosty weather the plants may

be removed to cold frames. They should be quite near to the glass and always have as much light and air as possible except on very cold days. Any time in December the plants can be removed to the forcing house, a temperature of 45° to 50° will suit the plants perfectly at first. Watering and ventilation should always be carefully attended to and a syringing under and over the foliage will be very beneficial and check the attacks of red spider. As the flower trusses begin to show, the temperature may be increased to 55° to 58° and the syringing should be discontinued after the blooms open. When the fruits have set well, only the larger ones should be retained for ripening, all the small ones being removed from each truss. To assist the plants at this stage a little liquid manure may be given about three times a week until the fruits begin to color. Then pure water is best. The plants need not all be forced at the same period, this may be arranged by taking a few from the cold frame at intervals of a week or a fortnight as required.

THE CULTURE OF BEARDED IRISES

THOSE who have grown the old German Irises for years and been uniformly successful with them although they have never spared a thought as to their culture, will doubtless smile at my title. It is of course, true that in certain rather light, clean soils these plants will flower freely and the blossoms will be little out of character, even though the only attention they receive is lifting and dividing when they become excessively overcrowded.

Not everyone, however, has such natural soil, nor will the possessor of such find it of much avail should his plants unhappily become infected with rhizome-rot. To obtain the best results with these Irises, particularly as regards size of flower, the soil should not be over-light; it should, on account of the "rot" danger, contain a fair percentage of lime, but it should **not** contain any appreciable content of humus. Drainage should be free, the site where they are planted open to sun and air, and the rootstocks should at no time be buried to more than half their depth.

There seems no doubt that varieties which are shy to flower—and some of the newer ones are rather shy—flower best when planted in full sun and left to establish themselves for a year or so, but there is wide scope for systematic investigation as to the comparative requirements of the different sections. Personal experience would suggest that the squalens and variegata sections are more weatherproof than the stately pallidas and trojanas, for instance. The former appear to withstand with greater equanimity—if the word may be pardoned—Summer heat and Winter wet.

The same remark will apply with equal force to planting times. It is by no means clear which is, in fact, the best planting season—indeed, there are considerable differences of opinion on the question—but may not the fact be, after all, that different sections and, since so much intercrossing has taken place, different varieties, even though somewhat similar in appearance, transplant best at separate seasons?—*The Garden*.

A cheerful temper joined with innocence will make beauty attractive, knowledge delightful, and wit good-natured.—*Addison*.

THE LITTLE GARDEN

TO a thirsty man a few cups of water are better than an ocean which he can swim in but cannot drink. The widespread love of flowers—would that it were universal and more intense!—is better satisfied by the purity and freshness of a few choice blooms than by a wide area of extensive planting. The former meet a necessity; the latter provides for enjoyment. Yet the ocean has its value. Without it the winds which travel to the four corners of the earth would everywhere pass over a desert. The winds of the gardening world blow over the area of extensive culture and gather up its essence, bearing it to distant regions to feed the springs which bring refreshment and beauty to many an otherwise barren spot.

These springs are the little gardens. Though measured in rods they are in no way to be despised in comparison with those which are measured in acres. Nature is infinite, and size is nothing in her presence. The more one is in sympathy with the spirit of Nature, which is the spirit of true gardening, the more evident becomes the potential value of the little garden.

It is a matter of common observation that the greatest specialists among us are the greatest enthusiasts. The treasures which gardening holds are scattered widely, but also buried deeply so that the pearl diver who confines his attention to one spot may easily reap as rich a reward as the explorer who sails round the world in search of variety.

A garden makes its strongest appeal when Spring flowers are first coming into evidence. This is partly because flowers are scarce at this time so that the few which do appear stir a deeper interest than their actual numbers would seem to merit. The attention they draw is concentrated and, therefore, intense, and is assisted by the more cheerless Winter background against which they appear.

Not alone by Winter, however, is a dull background provided. One has only to notice the condition of thousands of the enclosures attached to the everyday dwellings owned or tenanted by "the men in the street" to realize what neglected possibilities lie strewn on every hand. How different might our towns and cities be if only the romance dormant in a patch of soil were appreciated by every lucky owner of a "back yard."

We pride ourselves on being the greatest gardening nation in the world, but there is still room for us to prove that we can be great in little things. It is a reflection on the popularity of the pastime that the term "back yard" should have a derogatory meaning.

There lies a little patch of earth, neglected, down-trodden and hard as the heart of the owner, who sees in it no possible source of intellectual refreshment. Wonderful in its history and composition, richly stored with material which might be built into a living structure worthy of the admiration of a man, teeming with living workers and holding deeper secrets than the wisest among us have yet fathomed, it remains brown and bare beneath the oft-passing footsteps. Yet leave it entirely to Nature for a time and see what happens. Its life-supporting powers find expression and weeds appear. Where weeds can flourish fairer plants can grow.

No serious readers of this paper are likely to miss all the possibilities of the little garden, but it is doubtless in the power of many to influence others who do. If ignorance is the cause there is plenty of information which can be distributed freely with benefit to both giver and receiver.

If interest is lacking it can be stimulated by the healthy infectious enthusiasm of those who know the value of a garden, however small. Various forces are working to forward the movement, but personal influence is the most effective. Individually it may not appear much, but one of Nature's greatest lessons is the importance of little things—be they vitamins or eelworms!—*The Garden.*

JERUSALEM CHERRY

SOLANUM capsicastrum, or as it is popularly known, the "Jerusalem Cherry," is an evergreen greenhouse plant of dwarf compact habit, attaining with age a height of from one to two feet. It is what is known as an old-fashioned plant, but is rapidly coming again into popular favor, for when well grown and cared for it is a grand plant for the decoration of the greenhouse or window garden during the Winter months, especially during the holiday season, as its glossy scarlet berries are borne in the greatest profusion, and form such a contrast to the glossy green leaves that the name of miniature orange tree is often bestowed upon it. The glossy scarlet berries which are about the size of a small marble, commence to ripen about the end of September, and remain on the plant until the growth commences in the Spring, the flowers being quite small and insignificant, writes Charles E. Parnell in *The Flower Grower*.

This highly ornamental plant requires but little care or attention to grow it to great perfection, and is easily raised from seed which should be sown as early in the Spring as possible, in a well drained pot or pan filled with light loamy soil. Sow thinly, cover slightly, and place in as warm and moist a situation as close to the glass as possible. As soon as the young plants are large enough to handle, let them be transferred to other pans, or shallow boxes, similarly prepared, and placed in rows about an inch each way, and grown on until the weather becomes settled, when they can be planted out in a very deep well enriched bed, in a warm sheltered situation, and placed about 18 inches apart each way. If at all possible, give a light mulch of littersy manure and copious supply of water both overhead and at the roots during the Summer.

About the middle of September they should be very carefully taken up and potted, giving them well drained pots proportionate to the size of the plants. When first potted, water thoroughly, sprinkle freely and frequently for several days afterward. Keep them in a sheltered situation until they are brought inside, where they should be given as light and sunny a situation as possible, and an average temperature of 50 degrees.

If it is desired to carry the plants over for another year (and it is well to do so, as large specimens will be secured), let them be cut back to the desired shape and size early in May, planted out, and grown on, precisely as advised for seedling plants. As a result of the care and attention that has been given the Jerusalem cherry of late, the varieties known as Weatherill's Hybrid and Hybridum Hendersonii have been produced, and are quite improvements on the older sort; the former being of more compact growth, having darker green foliage and much larger berries; the latter being of a more dwarf, compact habit of growth, with berries more resembling an acorn in shape, and as a rule reproduces itself fairly well from seed.

When grown as pot plants the solanum should be given a rich-loamy soil, and during the Winter months carefully supplied with water, as if this is not properly done, and the plants allowed to suffer for a want of moisture for any length of time, or often, the berries will ripen prematurely and drop. The plants should be freely sprayed or sprinkled whenever it is convenient to do so.

From An Old World Garden

ARTHUR T. JOHNSON, F. R. H. S.

IF I were asked to state what are the most noticeable features of today in the trend of English gardening I should frame my reply very briefly somewhat thus: In the first place there is in most of our best gardens a decided leaning towards a modification of the old herbaceous border which has been so firmly established for nearly a century. The high rate of labor and material since the war has been a factor in bringing about this change, for no part of the garden is so costly to maintain as an herbaceous border. But there are other influences at work. With the introduction of so many new plants from all quarters of the globe by Wilson, Forrest, Farrer and others, there has arisen a notable partiality for the species, rather than the hybrid of garden origin. The enormous popularity of rock-gardening has, of course, helped to stimulate this preference, for your true alpine is always, or nearly always, a species.

Now this transformation in garden design suggests that there is a certain weakening in that appreciation of great displays of massed color to which we have so long been loyal, and it is so. Just as the old and gaudy carpet-bedding style went out with the Victorian Era, to be supplanted by something less formal and more pleasing, because less artificial, so we are gradually witnessing a process of evolution in the herbaceous border which promises to culminate in something very different. That we shall continue to have our Delphiniums, Phloxes, Antirrhinums and the rest there is no doubt. The demand for these is probably as keen today as it has ever been. New sorts are constantly being sent out. But our handling and treatment of them will be different. They will have to make elbow-room for those distinguished strangers, the species, which have so peculiar a fascination of their own, quite apart from what intrinsic beauty they may possess, and which we cannot resist.

In addition to the influence it has exercised in promoting an interest in species, the rock-garden has also been a magnet which has side-tracked many adherents of the old-style bed and border. Scarcely less might be said of the wild or woodland garden which is now so often a happy substitute for those dismal "shrubberies" which had neither use or meaning. Why, one would now as soon think of growing mustard and cress in the rock-garden as of bundling together in a chaotic mass, say, Wilson's Cotoneasters or Berberises, and calling it a "shrubbery." Indeed, it might be said that the semi-wild or woodland garden owes its inception to a great extent to these and other introductions in shrubs and trees.

The Ericas are a prominent feature of many such gardens as the above and I know of no more useful and ornamental race of shrubs. My own district being tolerably mild, there are varieties of Heather which will give us bloom throughout the year, beginning with *E. Darleyensis* in November and winding up with the handsome Corsican, *E. stricta*, in October. At the moment of writing (mid-March) *E. carnea* is covering a bank with a mass of its brilliant carmine-pink. This is extraordinarily hardy and the roughest wintry weather has no effect upon the beauty of the blossoms. *E. hibernica*, which is rather a lax-habited form of *E. mediterranea*, but with distinctly glaucous foliage, is also in full flower and the fresh, lettuce-green of the plumose *E. lusitanicus* (codonodes) is strung with its pretty white bells. *E. australis*, perhaps the most distinct and beautiful of all, is also opening its large urn-shaped flowers in vivid rosy-purple.

This is not hardy nor is the true species often seen.

But among all these and other Spring-flowering Heaths, *E. mediterranea* is doubtless the most satisfactory for general use and wide plantings, a great drift of its delicate rosy-purple having a most charming effect. It grows to about 3 feet with us, but there is a form known as *E. m. superba* which is larger and even more floriferous than the type, a most glorious shrub when in full bloom and one that will remain "on show" from early April to the end of May. (See illustration.)

Among flowers that last long *Vinca acutiflora* deserves special mention. This is a Winter-flowering Periwinkle, albeit a most accommodating plant, falling in with almost any circumstances with the best of good will. With us it started flowering last November and, the Winter being mild, it is still as good as ever. This is not a trespassing species, like *V. major*, but a well-behaved, easy-tempered species for any half-shady spot. It grows about 1 ft. and bears large flowers, snowy white with just a shade of cool lavender, or glacier-white, as some describe it.

Omphalodes cappadocica is another almost perennial bloomer and one whose azure is so pure and intense that not even *Gentian verna* can excel it. This species also has the special merit of being of easy culture. At the moment of writing there is a bed of this lovely Cappadocian Forget-me-not in full flower on our woodland slope. There it has seeded and spread so freely that it covers several square yards, and when I say that the wonderful blue flowers are each larger than a ten cent piece and borne in profusion on airy sprays some 6 inches high, the effect can perhaps be more easily imagined than described.

When on a recent visit to Kew Gardens I refreshed my memory of certain Ericaceous trees and shrubs with which I had become familiar on the Pacific Coast of America. One of these, *Arctostaphylos manzanita*, has now been awarded a first-class certificate by the Royal Horticultural Society, and few of its kind more fully deserve it. This may not be a showy shrub, but, like *Arbutus menziesii* and others of its allies, it has a unique charm. Here it attains a height of 8-10 feet, and maybe as much through; the buds form during the Winter and the panicles of pitcher-shaped blossoms—white, flushed with pink—appear in their full beauty in the early Spring. Now that *A. manzanita* has been brought before the public notice there is no doubt that it will soon become as widely grown here as some of its kindred, especially since it is hardy enough in light soil for any of our south and westerly counties.

Though travelers still search the ends of the earth for novelties I often wonder how many plants and shrubs there still are in California and other parts of America which have not yet been afforded the notice they deserve by European, and possibly American, gardeners. From my own travel experience on the American Continent I could enumerate a goodly list.

The pretty cup of the Anemone is so glossy it seems to burn with a white light. The secret of its incandescent beauty is that decided purple washing the outside of the cup. This dark background makes a reflector of the white cup so that it sparkles in the sunshine like a tiny mirror. Often the purple tinge seeps through to the inside of the cup, streaking it most daintily. As for the buds, they are rose and purple beads tipping their hairy fine stems. A group of wind flowers makes a dainty set for butterfly parties.—*C. S. Monitor.*

Origin and Varieties of Muskmelons

DURING the past few years numerous inquiries have been received at the Missouri Botanical Garden concerning the origin and names of the many varieties of muskmelons, and accordingly this article has been prepared with the idea of clearing up the confusion which seems to exist regarding the fruit.

The terms muskmelon and cantaloup are used in different parts of the country to designate entirely different kinds of melons. In the South the term cantaloup generally refers to all the varieties of muskmelons, whereas in the North it is more narrowly restricted to the larger, smooth, yellow-fleshed melon. In any case the use of "cantaloup" instead of "muskmelon" as a general term is incorrect, since all authorities agree that the cantaloup is only one of the subdivisions of the muskmelon. It is the general belief that many of the newer melons on the market, such as the Casaba and Honey Dew, are hybrids produced by a crossing of distinct species. This is not the case, however, since all true muskmelons have originated from a single botanical species *Cucumis Melo*, and there is probably no other plant which has produced such a variety of forms.

One of the most widespread beliefs is that the muskmelon and the cucumber readily cross and that if the two are grown in close proximity the pollen from the cucumber flower will have a deleterious effect upon the melon. Strangely enough, there has never been any report of the effect of the muskmelon pollen on the cucumber fruit, although one would expect the effect of crossing these two plants to be manifested in both directions. As a matter of fact, while the muskmelon and the cucumber are very closely related, both belonging to the genus *Cucumis*, attempts to cross these two plants have never been successful. It is not unlikely that various types of melons taste like cucumbers, but this is because they belong to the cucumber family and not because they have been hybridized with the cucumber.

Numerous attempts have been made to classify the muskmelon, but the one generally accepted is that prepared by Naudin. Naudin obtained material from all over the world and grew thousands of plants, and as a result of his investigation came to the conclusion that *Cucumis Melo* could be divided into ten groups. Among the edible are:

CANTALOUPS (Melon Cantaloups).—These are characterized by hard and scaly or rough skins and are usually deeply furrowed. The name is derived from Cantaluppi, a former country seat of the Pope near Rome, where these melons were introduced from Armenia. A considerable difference of opinion seems to prevail as to the spelling of this word, which appears as cantaloupe, cantaloup, cantaleup, canteloup, conteloupe, cantalope, cantelope, in various articles on the subject both in this country and abroad. Naudin spelled it cantaloup, and the weight of authority seems to be with this spelling.

NETTED MELONS (Melons Brodés).—This group includes the nutmegs and related forms which are grown so extensively in the northern states. The so-called "Rocky Ford" which belongs to the netted group is not a distinct variety, as is generally supposed. The "Netted Gem" melon was the original variety used to develop the Rocky Ford cantaloup. Years of selecting and crossing have greatly improved this type, and the Rocky Ford strains of cantaloups now possess both the green and salmon-tinted flesh. The so-called "Osage" type which appears on the market under the name Osage Melon originated near Ordway, Colorado, adjacent to the Rocky Ford district, and is sometimes confused with the true Rocky Ford melon. The former, however, is characterized by an orange-col-

ored flesh and is entirely distinct from the Rocky Ford type. Another important type belonging in this group is the Montreal Market, or Montreal, which was developed in Canada. This melon, because of its fine flavor and keeping qualities, is in great demand.

WINTER MELONS (Les Melons d'Hiver ou Melons sans Odeur).—It is to this group that the Casaba and Honey Dew melons belong. Until comparatively recently the so-called Winter or scentless melons were seldom, if ever, grown in this country. They were regarded as being of inferior quality, and practically their only advantage was their keeping quality. For this reason they have been a favorite variety in Spain and Southern France, where they are grown for the Scandinavian, Russian, and other northern markets. The Casaba melon, also spelled Kasaba, Cassaba, Cassabad, and Casba, was named for the town of Kassaba, some twenty miles from Smyrna. About 1878 seeds were sent to California by travelers who had tasted the melons in the hotels of Smyrna. From this beginning hundreds of acres of this variety are now grown each year, principally in the San Fernando Valley of southern California. They come into the market after the ordinary cantaloup has disappeared and are frequently shipped as late as December or January. The Honey Dew melon is an old south-of-France variety and it is listed by the French seedsmen under the name of White Antibes Winter Melon. At the present time it is most extensively grown in California. The Winter melons are characterized by their lack of odor and greenish or pale pink, rather than reddish orange, flesh.

While the classification of Naudin is still the standard for students of the species *Cucumis Melo*, for purposes of convenience it has become customary to divide the commercial muskmelons into two groups—namely, the netted and the scaly-skinned varieties. The netted group, known as nutmeg or netted melons, comprises those usually grown in the North for the home garden and early market. The scaly or furrowed group contains the longer-season varieties, and the term cantaloup is correctly applied here.—*Missouri Botanical Garden Bulletin.*

DAPHNE CNEORUM

ALTHOUGH a little tender in the North, *Daphne cneorum* is one of the best low growing shrubs. There is a great difference in strains, however, some blooming much more freely than others. It is well worth while learning something about the strain your nurseryman sells. The dark green foliage and terminal heads of this daphne, smothered with bright rose-colored flowers with a powerful fragrance, attract the attention of everyone when the plant is in bloom. Nothing is more beautiful in the rock garden; it is equally good when grown in a border. Yet it is very particular about soil. No plant I know dislikes chalk or lime more. When the plants get aged and worn lay the tops of the young shoots in sandy soil, leaving them for two or three years, when they will make fine young specimens. I always found when the plants had attained age they transplanted unsuccessfully, whereas young ones soon established themselves after re-planting.

—*Horticulture*

Do you find the columns of the GARDENERS' CHRONICLE interesting? Certainly you do, or you would not be perusing them. Your gardening neighbor, were he familiar with them, would become equally interested. Why not recommend the GARDENERS' CHRONICLE to him as a guide to his garden work? He would appreciate it—and so would we.

The Changing World of Plants

WILLARD N. CLUTE

OUR forest trees, at once the oldest and most ambitious of Nature's experiments in the vegetative line, have long been on the decline. Not only are there fewer species in the world than formerly but there are fewer individuals. In spite of extensive efforts at reforestation their numbers continue to grow progressively less. Once trees seem to have covered practically all the earth. They formed the dominant type of vegetation; in fact, they may have been about the only forms of plants in existence for few remains of other plants of that far away time have come down to us. The monstrous lizards and other gigantic creatures that once shared the earth with them have gone the way of all things and now the trees are clearly following the same road.

In view of the changes that have taken place in the make-up of our flora and fauna one might be justified in wondering whether each species, as well as each individual may not have its own very definite life-cycle which after a certain period of time causes it to give way to other and newer forms. It is undoubtedly true that certain forms of life are more primitive than others. Such forms seem but poorly equipped for the battle of life as it is waged at present. The kangaroo and the duck-bill come to mind as illustrations from the animal kingdom and among vegetables many of the catkin-bearing trees are in the same category.

Since the arborescent flora is the climax of vegetable activity, it is naturally most numerous as to species, most varied as to form and structure, and most abundant as to individuals in the warmer parts of the world where all the conditions for growth are at their best, but trees are by no means dependent upon especially favorable conditions. The hardy birches, willows, and aspens, though greatly reduced in size and abundance do not shun even the lands beyond the Arctic Circle and there are a great many others whose range is entirely outside the tropics. In the Arctic regions and in extra-tropical lands generally, however, the trees are outnumbered by those up-start newcomers, the herbaceous plants. Time was when they appear to have had no competitors but little by little these more modern species have pushed in, perhaps not so much crowding the others out as occupying any space their diminishing numbers left vacant. But in the tropics the trees still make a brave stand. The prevailing type is a woody one. It is said that only one species in a dozen there is herbaceous.

The trees that first inhabited our globe are now practically extinct. The ferns, scouring-rushes and similar plants were once of tree-like proportions and those we call conifers were much more abundant and widespread. A few of these latter are still represented on the earth. It is possible that there were not as many different kinds then as now, but their modern descendants though more varied in form to fit many varieties of environment that have since arisen are still fighting a losing battle and are being pushed steadily down the road that leads to oblivion. The end has been hastened rather than delayed by that tool-using animal, Man, who has thrown the weight of his activities into the scale against them, felling them by the thousands and cutting up their dead bodies to serve his own purposes.

That the trees lack the aggressive spirit of more modern vegetation is seen in the almost total inability to extend their present areas. There is very little of the weed in the trees. A few may push in where they are not wanted, but a group they hold themselves aloof from such matters. The box-elder comes very near to being a

weed in some places, the ailanthus, an immigrant from the Orient, is like all immigrants fond of colonizing in any convenient place and the elm and cottonwood may spring up in open places ready to contest their right to the spot with all comers, but this is nearly the complete list. We wonder what will kill the weeds, but as regards the trees, we ask how to make them grow!

It is not contended that trees will not spring up in new regions adapted to their growth, but that they have to have specially favorable opportunities for it. Thoreau long ago showed that broad leaved forests are likely to follow coniferous forests and vice versa. One incubates the other, as it were. Under ordinary conditions a slight change may cause one group of plants to give way to another. A small difference in the moisture content of the soil or the presence or absence of a single mineral, may make possible a very different plant covering. Thus the chestnut is inclined to avoid soils containing limestone and various heaths absolutely refuse to grow in them. Lowering the moisture content of the soil may cause ashes and walnuts to replace cottonwoods and willows and similar differences determine whether red or jack pine shall inhabit a given area.

One of the most important differences in the plant covering due to varying amounts of moisture in the soil is seen in the division it makes between the broad-leaved and needle-leaved trees. The trees with slender leaves, like the pines and spruces evaporate water very slowly and are thus able to survive and to retain their leaves in either cold or dry regions. So far as the trees themselves are concerned, cold regions are really dry ones, for though there may be water in the soil in Winter, the trees can get none of it. When conifers and broad-leaved trees inhabit the same general region, the conifers will be found in the driest parts. At first glance this statement seems in error, for almost anybody can recall conifers that thrive in wet places. In such cases the soil is probably dry so far as the plants are concerned by reason of various acids or other substances in the water that prevent the ready absorption of moisture. Thus it happens that some swamps and bogs may be veritable deserts to the plants that inhabit them.

Although the forest trees usually produce seed in abundance, a remarkably small number sprout and grow. This does not seem to be because the seeds lack vitality, but because for some reason the young plants fail to find encouragement in the world. It is to be noted that those which have adopted light and readily distributed seeds are those most likely to extend their territories; in fact, it seems probable that without interference from man, the plants with wind-distributed seeds would in time supplant those with other means of distribution. Think how much more rapidly the seeds of cottonwoods can move into a locality than the seeds of the walnut and oak. Still, when conditions are propitious, even heavier seeds than the walnut may move into far distant lands. This is true of the coconut, whose large seeds, borne by the sea, have penetrated to the most distant lands within the tropics. But when we consider the means of distribution possessed by the coffee-tree, the osage orange, and similar species, we do not wonder that until man voluntarily spread them for his own uses, they occupied a very small area in comparison with some of the others.

Our grand business is, not to see what lies dimly at a distance, but to do what lies clearly at hand. — *Thomas Carlyle.*

A RARE ORCHID COLLECTION

WHAT is without doubt the finest orchid collection in existence today in the southern states is that of Mr. and Mrs. Asa G. Candler, Jr., which occupies two sections of the greenhouses on their estate at Atlanta, Ga. One section consists of species exclusively, covering a very complete list of *Cattleya Trianae*, *C. Mossiae*, *C. labiata*, *C. gigas*, *Oncidium*, and *Vanda*, which are grown mostly for cut flower purposes. Among the *Vanda cœrulea*, one flowered with two spikes last Fall, carrying thirty-two blooms.

The hybrid section contains a choice collection of which mention must be made of the following: *Brasso-Cattleyas* such as *B-C. × Manda*, *B-C. × Empress of Russia*, *B-C. Siren*, *B-C. Lotus* (very rare), *B-C. Calypso* (very

Brasso-Cattleya, Hene, of the collection of orchids belonging to Mr. and Mrs. Asa G. Candler, Jr., Atlanta, Ga. (James Barnett, gardener.) This flower measured full $9\frac{1}{2} \times 9\frac{1}{4}$ inches.

scarce), and *B-C. × Nestor*; *Cattleyas* such as *C. × Adonis C.*, *C. × Lord Rothschild*, *C. × Prince John*, *C. × Princess Royal*, *C. × Golden Oriole* (a very beautiful orange yellow variety); *Lælio-Cattleyas* such as *L-C. × Australia*, *L-C. × Bella*, *L-C. × Delight*, and so forth, comprising in all about three hundred of the best hybrids.

The collection, which was supplied by Julius Roehrs Company, is one that is greatly appreciated by Mr. and Mrs. Candler, Jr., both of whom are keenly interested in the orchid.

ORCHID EXPEDITION TO TROPICS

GEORGE H. PRING, the horticulturist to the Missouri Botanical Garden, has started for Panama and Colombia for the purpose of organizing an expedition into the mountain regions of parts of South America to collect orchids as well as certain interesting economic plants. Before making such a trip it was necessary to obtain a special permit from the Federal Horticultural Board of the Department of Agriculture, in order that the *Cattleyas* and other orchids best known to the public might be admitted. These plants, with many others, were formerly imported by the thousands, but since the enforcement of

"Quarantine Number 37" very few have entered the country. The fact that the Missouri Botanical Garden is prepared to combat any injurious insect or fungous pest which may happen to inhabit the collected specimens was undoubtedly a factor in obtaining the necessary permit.

During the recent annual orchid displays the visitors have repeatedly manifested a desire to see an exhibition of orchid flowers arranged in masses, similar to the chrysanthemum show. The habits and manner of growth of orchids do not permit their propagation in the same way as chrysanthemums, and it is necessary to secure the plants from their native home. Therefore, in order to bring the orchid show to the same high degree of excellence as the "mum show" and similar exhibits it becomes necessary to obtain the popular favorites in quantity. With this in view the expedition to the tropics is being planned. The genus *Cattleya* includes many species which flower at different months of the year.

The favorite haunts of the various species of *Cattleya* are the mountain ranges of Colombia, Venezuela, Guatemala, Ecuador, British Guiana, and Brazil, each variety being practically indigenous to a special locality. The species most desired at the Garden are those flowering in January and February, and these are *Cattleya Trianae* and *Cattleya Schröderæ*. The former is found in the upper Magdalena near Natagaima on the Saldana River of Colombia and the latter in the Llanos de Cassanare on the Venezuelan border of the same country, two widely separated regions particularly when the difficulties of transportation are borne in mind. Despite this fact it is hoped that sufficient plants may be collected and brought back to St. Louis, so that the most notable exhibition of orchids ever held at the Garden may be made during the early part of 1924.—*Missouri Botanical Garden Bulletin*.

DELPHINIUMS AND DEEP CULTURE

THE failures I have met with have all been through lack of appreciation as to the requirements of these quick-growing herbaceous subjects. On loamy soils it is not a very difficult matter to conserve moisture, and it is when such provision is made for *Delphiniums* that the roots find sustenance deep down throughout the period prior to blooming. We are not all, however, in the happy position of having a loamy soil to deal with. Some have to contend with a soil of a sandy or gravelly nature, through which water quickly percolates, and *Delphiniums* betray lack of food. It is all the more reason why any deficiency should be made up to them, as in the absence of food, no flowering plants in the garden cut so sorry a figure as these. Even those who are handicapped in the nature of their soil can obviate to a very large extent any possible failure with these plants by working into the base vegetable refuse as well as manure.

One of the lessons I learned early in life was the manner in which a good grower of *Delphiniums* treated his shallow soil by making use of decaying vegetation and in mulching the roots during the growing season. There is one point which is sometimes overlooked concerning these plants, and it is the rapidity with which most of them grow, necessitating the clumps being divided at certain intervals if they are to be kept within reasonable limits. It is not unusual to see large clumps carrying far too many spikes, the centres being poor and indifferent, consequent on their not being able to obtain the needful moisture. It is the moderate-sized clumps, with a cool run that always make for beauty in a garden.—*Gardening Illustrated*.

IN APPRECIATION OF ANNUALS

THE culture of hardy and half-hardy annuals is regarded more seriously than in former years; indeed, few English gardens are now reckoned complete without a liberal quantity of these short-lived plants. Time was when annuals were regarded with more or less contempt, except in the case of such subjects as Asters, Balsams, and the so-called florist's flowers. Of course, the skilled attention of hybridists and specialists has had much to do with their increased popularity. Who will deny the rapid advance that has been made in the development of annuals during the past decade? When we come to consider the marvellous creations which have been evolved in such races as Clarkia, Larkspur, Candytuft, Godetia, Chrysanthemums, Lupin, and a host of others we cease to wonder at their repute. But this is not the only reason why annuals have come to be more favorably regarded. The somewhat tardy recognition of their adaptability to the modern and less formal style of gardening will largely account for their present position in the popular taste.

By judicious and successful sowings in Autumn and Spring it is possible to have a display of annuals from April until far into the Autumn. This alone is a recommendation. In the perennial border, too, they may be made to serve a useful purpose. By sowing suitable kinds between the permanent occupants, so as to give a show of bloom before or after their associates, one is soon made aware of their utility. In the rockery, also, many kinds may be introduced for the same purpose. Indeed, several sorts are seen to the best advantage when growing among stones, while they certainly find a more congenial home when growing in the bed or border. Many rock gardens are particularly bare at certain seasons of the year, but there is no lack of annuals for providing the continuation of bloom which will fill these uninteresting periods. And so we have annuals for all purposes. The border in shade is as easy to cater for as the one in full sunshine, while suitable sorts can be found for dry or moist situations. Neither should we overlook the value of annuals for cutting. Many kinds are valuable for cut bloom, and, as everybody knows, the periodical cutting of bloom is really the best way to prolong the flowering period. Then, again, we have a wealth of sweetly scented annuals which contribute much to the charm of the garden.

I suppose the chief reason why annuals were once in disrepute was the lack of attention bestowed on their culture. Any sort of cultivation was considered good enough for these short-lived plants. It is now recognized, however, that good culture and generous treatment are worth while in growing annuals. As a matter of fact, the ground should be prepared for them as thoroughly as it is for perennials. Many annuals under good treatment compare quite favorably with some of the choicer kinds of perennials.

There is one point I would emphasize in regard to growing annuals. As they are short-lived plants, any errors of culture or neglect in timely attention cannot be repaired as in the case of perennials. The matter of sowing, thinning, and transplanting, the removal of dead flowers, and all the minor details of culture must be seasonably and properly performed in order to be successful. To remove the flowers before seed matures is particularly important. The reader is reminded that the function of a plant is to reproduce its species, and after it has attained this object there is no further need for its existence. Therefore by deferring this process for as long a period as possible we are prolonging the life of the plant, and incidentally inciting it to further efforts at flower production. There is considerable scope for the beautifying of gardens by the employment of annuals, and many pleasant surprises are in store for those who are willing

to pay for seed of the best strains and who will devote care and patience to raising and growing them.—*Gardening, Illustrated.*

GARDENING UNDER GLASS

THE writer has often heard experienced gardeners remark that there is such a variance between out-door and in-door plant culture that a thorough knowledge of one does not supply the necessary knowledge to succeed with the other, and that both require separate experience and practice. It remained with a well known writer on horticultural subjects, F. F. Rockwell, himself an enthusiastic gardener, to contend in his book just published, entitled "Gardening Under Glass," that if you have been successful with your plants and flowers out-doors, you can be successful with them under glass.

Expert growers, those who grow the wonderful specimen plants which we see exhibited at the big flower shows, will refute such a statement as being ridiculous, and from their viewpoint they are absolutely correct, for only after years of experience have they acquired the ability to produce such plants. But those who grow merely for the pleasure they derive from it, are not thinking of competing with the experts whose equipment is usually different.

After one reads "Gardening Under Glass," he really feels that all he requires is a greenhouse and all will be easy. One who loves to work among flowers will find this book a most helpful and inspiring guide. True, like the bride with cook book in one hand and kitchen utensils in the other, he is bound to meet with some disappointments in his first efforts, but with a little perseverance, success will follow his endeavors with the pleasure it brings.

The book is entertaining as well as instructive. It is not filled with technical phrases that are foreign to the layman but it is worded in language so understandable that one feels it is all so simple that he at least cannot fail to have a lot of fine plants equal to those of the more experienced gardener. It is a volume full of inspiration and encouragement.

Mr. Rockwell covers every subject that enters into "glass gardening" from the "fascinating art of soil building" to growing fruits in pots twelve months of the year. Ventilating, heating, watering, plant foods, plant enemies and their control all receive careful consideration, assuring the reader that there is nothing to worry about when once he knows how.

The chapters on how to grow flowers for cutting, flowering and foliage plants, bulbs, fruits and vegetables under glass, are so instructive as to make the book invaluable to any one owning a greenhouse or contemplating having one. There are chapters devoted to what can be accomplished the year round; chapters on all kinds of greenhouses and what can be grown therein. The illustrations are many and show glass gardens that are within the reach of those of moderate means as well as houses more elaborate to conform to any style of architecture. They also show how much and how varied a collection can be grown in a small house by any one so fortunately equipped.

The writer advises anyone who has desired a greenhouse, but who has hesitated for fear that he would not know what to do with it after he owned it, to read the book, "Gardening Under Glass." Then he will no longer hesitate. Practical gardeners who would welcome suggestions to guide them in their greenhouse work the year round will find this book a most helpful aid. It costs \$3.50 and may be attained through the GARDENERS' CHRONICLE.

Foreign Exchange Department

VARIEGATED FOLIAGE.—One does not regard anæmia as an agent enhancing beauty in the human subject; on the contrary, every effort is made to counteract the mischief. Why, then, will florists perversely promote its equivalent—deficiency of chlorophyll—in plants? The few phanerogams, *i. e.*, flowering plants, which are normally devoid, or nearly so, of chlorophyll, are degenerates, either saprophytes like the Bird's Nest (*Neottia*) or thorough-going parasites like Dodder (*Cuscuta*), drawing nutriment from the store honestly accumulated by other plants by means of the chlorophyll in their foliage. Nevertheless, I venture to plead for one exception to the rule in this matter. The Golden Queen Holly, a variety of immemorial antiquity, when well set with scarlet berries, is no unworthy companion and offset to the natural green type.—*Gardening Illustrated*.

VIBURNUM CARLESI IN POTS.—There are few lovers of sweet-scented flowers who do not long to grow some of the choice Daphnes. Where they fail with the latter the above-named variety of *Viburnum* may be substituted, and certainly both kinds of plants should be included in the collection if this be convenient. *Viburnum Carlesi* is very free-flowering, pure white, and very fragrant. There is one drawback with regard to the plant itself, namely, the paucity of leaves at the time of flowering. As a pot plant in the greenhouse the lack of leaves will not be very noticeable if other well-foliaged specimens are judiciously arranged near. I think that more of the free-flowering shrubs that are suitable should be grown in pots specially for the cool greenhouse or conservatory.—*Gardening Illustrated*.

SHIRLEY POPPIES.—These have been improved almost out of recognition, and that they give a magnificent display cannot be disputed. Very few plants give such a wealth of bloom for cutting, and if the blooms be ephemeral, yet, so long as seed pods are not allowed to form, there are always fresh supplies. Many permit Shirley Poppies to grow too thickly and neglect providing supports for the plants. Let the plants be thinned until every one has at least a square foot in which to develop, and then put Spruce twigs or similar material thickly among the plants. These twigs may be 2½ feet in height, and as the Poppies make progress, the supports will soon be hidden from view, and the plants will be protected alike from rain and from gales.—*Gardening Illustrated*.

SHRUBS UNDER TREES.—In making a selection of shrubs for such a purpose it is necessary to know whether the trees are of dense growth, under which very few plants will thrive, or thin-headed trees under which numerous kinds may be grown. As a general rule, most shining-leaved shrubs will thrive as undergrowth beneath the shade of trees, but, in any case, the soil must be well prepared for them at the outset. If the trees have been planted within recent years, and the soil is tolerably good, but little preparation is necessary beyond deep digging; but if the trees are large and old, then the soil will be found overrun with roots and impoverished. In this case fresh soil should be substituted (say, from 9 inches to 12 inches deep), and in this the shrubs intended for undergrowth should be planted. The small shrubs should be vigorous and with plenty of roots, and the best time to plant is during September and October, allowing the leaves that fall from the trees to remain among them through the Winter. The choice may be made from the following list: Common Holly, *Berberis Aquifolium* or Mahonia, common Box, Oval-leaved Privet, Portugal Laurel, *Rhododendron ponticum* (if no chalky matter is in the soil), *Cotoneaster Simonsi*, *Skimmia oblata*, *Berberis Darwini*, *Berberis japonica*, and common Yew. All these are evergreen, and may be obtained at a cheap rate in nurseries. For very dense shade we have found nothing better than the Butcher's Broom (*Ruscus aculeatus*), with an undergrowth of the creeping St. John's-wort (*Hypericum calycinum*), Periwinkle, and Ivy. The common English Ivy grows naturally in dense shade, but the Irish Ivy has a bolder effect. *Gaultheria Shallon* may be planted in light or peaty moist soil, and a good carpet-like growth may be had of *Euonymus radicans* and its variegated form. There are few deciduous shrubs that will grow under trees.—*The Gardeners' Chronicle* (British).

FRAGRANT PLANTS IN THE PAVED PATH.—For planting between the stones of the paved pathway, there is nothing better than some of the fragrant plants. It is needless to enter into detail of the plants which may be so utilized, but the Thymes may be mentioned as invaluable, especially the smaller species and varieties, for there is nothing better than the tiny but highly perfumed *Mentha Requieni* (syn. *Thymus corsicus*). It is difficult to keep the paved path free from grass and weeds if the joints are left open, and I would suggest cementing the joints, only leaving a sufficient number of openings for the plants desired. This will save an immense amount of work in the future, and if more

plants are desired, additional openings can be easily made.—*Gardening Illustrated*.

PRUNING NEWLY-PLANTED TREES.—To prune or not to prune is the question. Is it better to inflict two hardships at the same time upon a tree or one hardship? There can scarcely be a doubt in an impartial and thoughtful mind as to the answer. What are the facts? A number of young trees has been lifted in order that they may be replanted 20 yards or 200 miles distant. Some injury or check has been given to the root-system of the tree, even if it did not lose a rootlet or part of a rootlet. The mere exposure to the air will cause a check to the activity of the root-system. If that be so in the case of trees lifted with the greatest care and regardless of cost, how much more is injury caused when a tree loses a distinct portion of its root-system in the act of lifting, as occurs in hundreds of thousands of cases every year! It is well, therefore, to recognize the fact and to take thought accordingly. It is beyond question, then, that a tree which has been transplanted has suffered some injury to the roots; and we are dealing with the question of pruning that tree and the time of performing the operation. My advice is—defer the operation, at all events, until the sap is circulating from the roots to the branches in Spring, and which is shown by the distinct swelling of the wood-buds near and at the ends of the shoots of this year's growth. Many young fruit trees have perished from no other cause than that of pruning at the time of—or soon after—planting.—*Gardening Illustrated*.

Horticultural Jottings

The fruit of the mayflower, or trailing arbutus, is reputed to be of rare occurrence. Certainly it is rarely seen; it has hidden itself for centuries among the leaves and moss. To be found, it must be sought lovingly, if not indeed reverently, upon the knees. Furthermore, it must be sought at the right time, and that time is when wild strawberries are ripe.

It is a curious and remarkable fact that a plant so universally known and so well loved for the beauty, charm, and fragrance of its flowers, should have been unknown as to the character of its fruit. Before the year 1913 none of our botanists adequately and correctly described it. The mayflower has not a dry pod, but a white-fleshed edible fruit as juicy as a strawberry, though of smaller size.

The Japanese have surpassed us in this matter, for they class their species of trailing arbutus as one of their edible wild fruits.

The fruit of the mayflower is not in reality rare. I have found hundreds of them in a woodland pasture in New Hampshire in a single forenoon.—Frederic V. Coville, in *The National Geographic Magazine*.

An old-fashioned flower garden will be a feature of the White House grounds this year, in compliance with a request made by Mrs. Harding. The garden is now being laid out and will contain chiefly the flowers that grew at her Marion home, of which she is especially fond. The new garden will be located in the eastern part of the rear yard, at a point not far distant from the White House Rose garden, and in it will be grown such homey plants as Morning Glory, Pansies, Forget-me-nots, Asters, Snapdragons, Foxglove, etc. Mrs. Harding is especially fond of Hollyhocks and Lilies of the Valley, and for these two special beds will be arranged immediately adjacent to the gardens proper. Another feature of the White House gardens during the coming summer will be the Mrs. Harding Rose, which was raised in the Department of Agriculture grounds.—*Florists' Exchange*.

Old Tut-ankh-Amen died about 3,000 years ago, but in the National Park of California are two Sequoia trees, the General Grant and the General Sherman, that were born about 1,000 years before the Egyptian monarch and they're alive yet. What's the use of going to Egypt to see old dead things when you can see older live ones in your own country?—*N. Y. Times*.

To commence preparations for a centennial celebration fifty years before the actual date would seem a trifle premature in the ordinary instance, but in the case of Arbor Day, to be observed in 1972 under the auspices of the American Tree Association, it is perfectly natural because it takes at least five decades for many trees to attain maturity. Aside altogether from the aesthetic aspects of the campaign, however, the economic angle should not be forgotten. What is the value to a city, that is to say, of many trees planted in its midst? Springfield, Mass., which is said to have more trees per inhabitant than any other American city, lists its 25,000 trees among its financial assets at a total of \$2,500,000. This fifty-years-ahead campaign is one which should exercise a wide appeal and deserves an enthusiastic response.—*C. S. Mottor*.

National Association Of Gardeners

Secretary's Office, 286 Fifth Ave., New York

1923 Convention, Pittsburgh, Pa. (Date not decided.)

The aims of the association are to elevate the profession of gardening by improving conditions within it.—To cement a closer bondship among all engaged in, and interested in, gardening—to create a greater confidence between employer and employee.

Co-operating with the Massachusetts Agricultural College, the association conducts a course in training young men for the profession, whereby they obtain theoretical knowledge as well as practical experience.

OFFICERS 1923

President JOHN BARNET, <i>Sewickley, Pa.</i>	Vice-President WILLIAM GRAY, <i>Newport, R. I.</i>
Secretary M. C. EBEL, <i>New York, N. Y.</i>	Treasurer MONTAGUE FREE, <i>Brooklyn, N. Y.</i>

CLEVELAND, O.: R. P. Brydon, chairman; George Wyatt, Painesville, secretary.

TRUSTEES AND BOARD OF DIRECTORS MEETING

During the week of the New York Spring Flower Show, a meeting of the Trustees and Board of Directors was held at the Murray Hill Hotel, New York. The meeting occurred on March 13 with the following members of the Board present: Robert Cameron, George F. Stewart, Massachusetts; Harold Bryant, Connecticut; John Barnet, John Tonkin, Pennsylvania; Robert Brydon, Ohio; Alex Michie, James Stuart, H. E. Downer, Montague Free, New York; Thomas W. Head, Arthur Smith, D. L. Mackintosh, M. C. Ebel, New Jersey. President John Barnet presided.

President Barnet called the meeting to order at eleven o'clock.

After the routine business, such as the reading of the minutes of the last meeting, reports of the secretary and treasurer was disposed of, there was a general discussion regarding the affairs and future policy of the association. Mr. Cameron spoke for the Committee on Training Young Men, reporting that considerable interest was being manifested in the course conducted at the Massachusetts Agricultural College in co-operation with the association and that while the attendance for the first year was not large, it is expected that the enrollment will be increased for the coming year.

The interest and general activity that has developed among the local branches was favorably regarded as showing that the gardeners in different parts of the country are beginning to realize what an important factor for the welfare of their profession these branches can be made. They give the gardeners who can not attend the annual conventions an opportunity to keep informed on what the association is doing and also a voice in its administration by permitting them to make recommendations to be submitted at the annual conventions. Mr. Head told of the meetings of the Morristown Co., N. J. and the Elberon, N. J. horticultural societies, which he addressed on the subject of the national association with a view to organizing a branch, and that the suggestion was so favorably received that the two societies decided to combine in organizing a local branch. Mr. Brydon reported on the enthusiasm with which the proposal to form a branch was received among the members of his locality, and of its organization. Mr. Stewart and Mr. Cameron spoke of the lively meetings and the good fellowship that prevails at the Boston branch meetings, stating that the last one had been so successful it had been decided to hold another within a month. President Barnet stated that the Western Pennsylvania Branch has interested itself in the coming convention with every member an enthusiastic worker towards making it a highly successful event.

The dates, August 14, 15, 16, 17, proposed by the Western Pennsylvania Branch for the annual convention were approved by the Executive Board. President Barnet announced that the Fort Pitt Hotel had been selected as the convention's headquarters.

A letter from William Gray was read, announcing his retirement from the professional fold to engage in commercial work, and accordingly tendering his resignation as vice-president, and accepted with regret. (By a strange coincidence, the sudden death of Mr. Gray, reported elsewhere in these columns, occurred on the day his resignation was being considered). President Barnet then appointed R. B. Brydon, of Cleveland, as vice-president, which appointment was approved by the Board.

At one o'clock the visiting members were entertained at luncheon by the New York and New Jersey members, after which the business session was resumed. Matters of special import to the welfare of the association and the gardeners in general received the attention of the Trustees and Directors, followed by a Round Table discussion which lasted till four o'clock. One of the interesting discussions was that of the gardeners' opportunity of attending the annual conventions, many contending that they find it almost impossible to get away from their work at any time. The members of the Board voiced the opinion, however, that in many instances it was due to the gardener not presenting his case properly to his employer; that the gardener is as equally entitled to his vacation as those engaged in other professions, and that if the employer were consulted, he no doubt would see the logic of such a contention. Another subject discussed was that of the apparent thoughtlessness of many employers towards their gardeners in the matter of remuneration, that some appear to overlook entirely the compensation of their gardeners while everything else that has mounted high in cost, has been generally accepted. It was the general opinion that while it might be possible to direct the attention of the employers to this oversight, it was a matter of negotiation between employer and employee, and as in other cases, would be remedied if presented in the proper manner.

Four o'clock came about entirely too soon, but as the out of town members desired to have an opportunity to visit the International Flower Show before returning to their homes, the meeting had to adjourn at that hour.

BOSTON BRANCH MEETING

A well attended meeting of the Boston Branch of the National Association of Gardeners was held at Horticultural Hall, Boston, on April 6, the second day of the Spring Flower Show of the Massachusetts Horticultural Society. Robert Cameron presided, and brought up the proper rate of pay which boys and college youths should receive while working on private estates. Mr. Cameron especially commended Italians as efficient and dependable workmen, James Marlborough, Stuart Forbes, George F. Stewart, A. K. Rogers, B. Hammond Tracy, W. N. Craig and others spoke on the subject. The consensus of opinion was that college youths were worth at least as much as ordinary laborers but much would depend on the boys themselves. Some would be more valuable than others and no flat rate could be recommended.

Mr. Cameron, Mr. Stewart, and Mr. Watt gave their impressions of the New York Show. Mr. Stewart spoke of the last directors' meeting held in New York and detailed business transacted. There was some discussion on the coming Pittsburgh convention and it was unanimously voted to hold a meeting early in August in advance of the convention and discuss possible timely subjects which might prove of interest to the annual convention.

W. N. CRAIG, Secretary.

CLEVELAND BRANCH

It has been decided to hold the next meeting of the above branch at the Alhambra Restaurant, Cleveland, on April 30, instead of May 7, as previously stated. The time will be seven o'clock.

GEORGE WYATT, Secretary pro tem.

WESTERN PA. BRANCH

A meeting of the Western Pa. branch of the National Association of Gardeners was held in the public school, Sewickley, on March 20. The secretary called the meeting to order and announced that owing to illness of the chairman, Manus Cufuran, was again unable to be with us. A motion was made and carried that David Fraser be elected chairman for the evening.

The chairmen of the various committees reported progress. Mrs. William Thompson was appointed chairman of the Ladies' Committee. John Barnet reported that the Executive Board had approved the national convention dates, August 14, 15, 16, 17, at the Fort Pitt Hotel, Pittsburgh. Mr. Barnet also gave a short but interesting talk on the New York Flower Show, which was greatly enjoyed by the members present. Our next meeting will be held April 17 at the Carnegie Library, Pittsburgh. A cordial invitation is extended to all members and friends to attend the meetings of the Western Pa. branch.—HENRY GOODBAND, Secy.

AMONG THE GARDENERS

H. D. Prosser has accepted the position of superintendent on the Paul D. Cravath estate, Locust Valley, L. I.

Charles Davis, foreman of the Daniel Gugenheim estate of Port Washington, L. I., has secured the position of gardener to Charles Guthrie, Reading, Pa.

Frank Jenkins, formerly superintendent of the L. B. McCarter estate, Rumson, N. J., is now superintendent to E. J. Dives, Reading, Pa.

William Chalmers, recently gardener on the A. K. Lawrie estate, Williamstown, Mass., has taken the position of gardener on the D. H. McAlpin estate at Morris Plains, N. J.

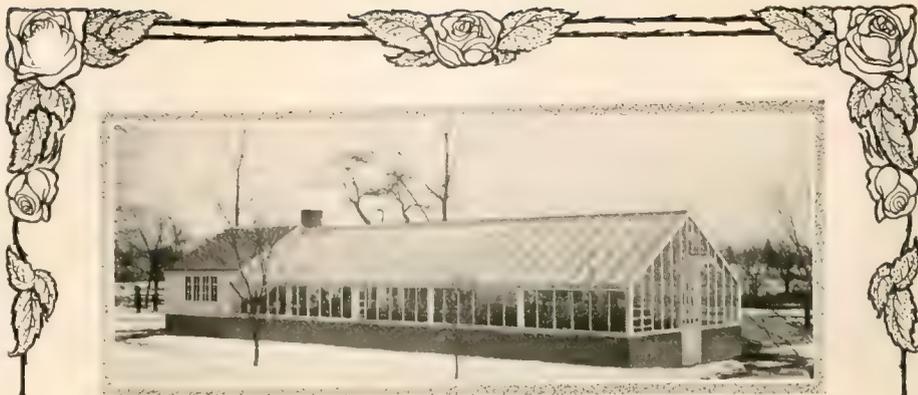

Charles Milburn has secured the position of gardener to William De Forest Manice, Old Westbury, L. I.

It was incorrectly reported last month that Martin Kuiper had accepted the position of gardener to Frank B. Black, Mansfield, Ohio. This position was secured by John Kullman, formerly of the H. S. Sherman estate, S. Conard, Ohio.

Jerome B. Murphy, until recently gardener of the W. B. Dickerman Estate at Mamaronck, N. Y., has secured the position of gardener on the Charles Hirshon Estate, New Rochelle, N. Y.

Alexander Douglas, formerly superintendent of the Lewis Forest estate, Nyack, N. Y., accepted the position of superintendent on the estate of Mrs. A. S. Mathew, Chardon Falls, Ohio.

George W. McGinnis, until the past year superintendent to Arden W. Hard Jr., at West Sayreville, L. I.

The Most Greenhouse For The Least Money

That is Practical

By the least money, we mean, the least that is consistent with lastingness and the making of a happy, healthy home for your plants.

It is a house we have been building for years.

A clean cut, thoroughly practical greenhouse, in which the ornamental touches and extra refinements, so to speak, have been eliminated.

Still, it is decidedly good looking, and will grow just as many

and just as fine quality of flowers as any house that costs more.

The times have made so many folks want to strip things for the running, as it were, that they quickly buy this Practical Purpose house, when they would not our regular one with its curved eaves and other features.

Thinking you might feel something the same way, here it is. Glad to send you fullest of particulars, or one of us will come and talk it over with you.

Lord & Burnham Co.

ONLY 4 Out of 100

plant lice were alive after one dusting with AXFIXO on potatoes. This is the result obtained by the New Jersey Agricultural Experiment Station, last year. You, too, can have the same results if you follow the simple directions on the container.

AXFIXO proves equally effective in the control of all plant lice, leaf hoppers, cucumber beetles, etc.

AXFIXO is a quality product at a modest price.

HIGHTSTOWN HARDWARE COMPANY
Hightstown New Jersey

Max Aubertel, formerly at Stamford, Conn., is now located as gardener at Wilburton Farms, Manchester Depot, Vt.

William Eccles, formerly superintendent of the Mortimer Schiff estate at Oyster Bay, L. I., and more recently of the F. F. Drury estate at Cleveland, has purchased the orchid growing establishment of Thomas Jones, Short Hills, N. J., and will devote himself to raising orchids for the market.

John Forbes, until recently superintendent of the A. V. Davis estate, Oyster Bay, L. I., has embarked in business for himself at White Plains, N. Y.

George Palmer, late of Lenox, has accepted the position of head gardener to Mrs. R. M. Saltonstall, Chestnut Hill, Mass.

William Gray, well known in gardening fraternities and until recently a resident of Newport, R. I., died suddenly at the home of his father at Middletown, N. Y., on March 13, to which city he had moved to assume charge of his father's florist business. Mr. Gray was vice-president of the National Association of Gardeners, and it seems a strange coincidence that on the day of his death his resignation, which he had tendered owing to his retirement from the gardening profession, was acted on by the Board of Directors. Mr. Gray came to Newport in 1893 and for the greater part of the intervening 30 years, except a brief time when he was employed on Long Island, had made his home here. He was first on the Twombly and Auchincloss estates, and after his return from Long Island was gardener at the Leeds estate, serving in that capacity until last Autumn, when the Princess Anastasia (Mrs. Leeds) sold the property to Mr. James B. Duke. Mr. Gray had been an active member of the Newport Horticultural Society, serving several years as recording and financial secretary, and last year was one of its vice-presidents. Not only had he been active as an official, but he was an exhibitor in the local society's flower shows and in Providence, Boston and New York. Specializing in sweet peas, his exhibits won many prizes and gave him a widespread reputation as a grower of this variety of flowers. He was courteous and obliging and won many friends by his willingness to help others with advice, material assistance and information.

Mr. Gray was born in 1874. He is survived by his widow and three daughters.

William Thomson, aged 70, died in his home, Sewickley, Pa., on March 9, following an attack of pneumonia. Mr. Thomson was born in Siggleshorpe, England, and came to America when he was 27 years old. He was engaged in gardening in Erie, Pa., for several years and later came to Sewickley to manage the garden of Mrs. Mary Copley Thaw on Sewickley Heights. For the past ten years he has been in charge of the greenhouses of the Joseph Craig estate.

Mr. Thomson comes of a family of flower-lovers, being the fourth William Thomson in the direct line to devote his life to horticulture; his eldest son, William Thomson, Jr., is in charge of the gardens and greenhouses of Mrs. William P. Snyder, Sewickley Heights. Mr. Thompson's widow, another son, Robert, and a daughter and two sisters also survive him.

Flower Show which is held every year in connection with the Annual Meeting of the Society.

An unusually comprehensive schedule has been prepared, offering generous prizes to both professional and amateur growers, for plants and cut flowers. In addition the Society invites original exhibits, particularly those of a decorative character, featuring arrangement for effect.

The show, which is held in the Main Building of the New York Botanical Garden, will be staged and judged on Friday, May 11, and will be open free to the public on Saturday and Sunday, May 12 and 13.

Schedules with prize list and full information are now ready, and may be had on application to Mrs. George V. Nash, Secretary Exhibition Committee, New York Botanical Garden, Bronx Park, New York City, or the office of the Society, at 598 Madison avenue, New York City.

NASSAU CO. HORT. SOCIETY

The monthly meeting of the above society was held on Wednesday, March 14, in Pembroke Hall, at 7 P. M. President James Gladstone occupied the chair. H. S. Freeman, of New York City, was elected to active membership at this meeting. Messrs. James McDonald, J. Michie and John Forbes judged the exhibits and their decisions were as follows: Twelve Pink Carnations, first, James McCarthy; twelve White Carnations, first, William Carter; twelve mixed Carnations, first, William Carter; three Pots of *Primula malacoides*, exhibited by James McCarthy, honorable mention. It was decided to hold a Tulip Show in May. The Chrysanthemum Society's rules will be used at our future Mum Shows. President Gladstone presented the Hitching Cup to Thomas Twigg. The cup was awarded at the Mum Show for four varieties, three of each. Exhibits for April meeting, six tomatoes; 12 mixed Antirrhinums; pot or pan, not to exceed ten inches, of Tulips.—ARTHUR COOK, Cor. Secy.

STAMFORD HORT. SOCIETY

The regular monthly meeting of this society was held on the 2d of April. There was a good attendance of members, and many fine exhibits were staged which brought out much discussion later in the evening. M. J. Quirk carried off the first prize with a vase of Hadley roses, also a cultural certificate for same. Other awards were as follows: M. J. Quirk, Ophelia 75 points, Columbia 75 points, carnation seedling and snapdragon very highly commended; *Didiscus cerulea* by W. J. Slade; carnation, Melville Francaise by A. Pederson.

Plans for a summer show were finally settled with much enthusiasm. At the mid-monthly meeting, April 17, President Gribelle of the Stamford Chamber of Commerce will lecture. The supper of the above society, held March 24, was a splendid success. The committee deserves great commendation and is now going ahead with its plans for the coming month to hold a Eureka affair. At the conclusion of the business a social hour was enjoyed. — E. W. WHITEHEAD, Secy.

WESTCHESTER CO. SOCIETY P. P. C.

The Westchester County Society for the Prevention of Cruelty to Children will repeat this Spring the series of Garden Days, held on Saturday afternoons during May and June throughout the county which proved so popular last year. These gardens extend from one end of the county to the other and consist of all garden types to be seen, from the large and formal garden to the small and friendly one, all of them a joy and delight to the true flower lover. All are

The Touch that Modernized this Quaint Old Colonial Home

THIS picturesque old Dutch house of red sandstone at Rochelle Park, New Jersey was purchased by Mr. Elmer B. Every and remodeled.

The improvement that most emphasized the contrast between Colonial and Twentieth Century modes of living was the installation of a Deming Home Water System with the resulting comforts and sanitary convenience of ample hot and cold water at the turn of the faucet.

The admission fee is only fifty cents which will all be spent to help and comfort little children of the county who are in sorest need of such aid.

WESTCHESTER (N. Y.) AND FAIRFIELD (CONN.) HORT. SOCIETY

The regular monthly meeting of this society was held in Greenwich, Conn., March 9. Quite a few members were present. One new member, George Bates, was elected for membership, and one proposed. Judging by the splendid exhibits at the past few meetings, there will be keen competition for the greatest number of points for the year. At the meeting, Edwin Beckett received first for a pot of *Phalænopsis Schilleriana*; W. J. Sealey, second for a standard *Heliotrope*, and John McCarroll, third, for a vase of *Stocks*. Other exhibits included vase of *Roses*, W. D. Robertson; *Primula obconica*, H. F. Bullpitt; *Sweet Peas*, Walter Slade; *Lupines*, John McCarroll. H. F. Bullpitt received first for two bunches of *Rhubarb*.

Progress for the Fall show is well on the way. James Stuart gave a very interesting talk on *Cyclamen*; his address led to considerable discussion. P. W. Popp gave an interesting talk on his last trip through the South and West, describing horticultural conditions prevailing in both parts.

A. KNEUKER.

TARRYTOWN (N. Y.) HORT. SOCIETY

This society held its meeting March 21, in the Corporation Building. The weather was ideal, and a full attendance was present. The exhibition tables were well filled with a large variety of plants and cut flowers. Alex. Anderson received first prize for *Sweet Peas*, as well as the prize for the best display in the hall other than *Sweet Peas*. He captured this prize with two large vases of very fine *Antirrhinums*. Other displays worthy of mention were some fine *Primulas* shown by John Honeyman, *Antirrhinums* by Mr. Fisher of Briarcliff, and displays of *Tulips*, J. Watterson, Thos. Lee and others. The judges were J. Featherstone, J. Watts and Wm. Graham.

Six nominees were elected to membership. Since our last meeting this society has lost a member in John Walker of Scarsdale, N. Y., who suddenly passed away through an attack of acute indigestion. After the reading of the notice, Pres. Wilson asked the members to rise for a minute of silence as a token of respect for our deceased member.

Tarrytown taxpayers have voted an appropriation of \$4,500 for the use of the society in carrying on the work which it started last year in the preservation of the shade trees of the town. This is a work which the society went into last year with such splendid results that it now has the backing of the largest taxpayers of the town. This beginning may lead to larger developments.

At this meeting the society voted to hold two shows this year, one in September and one in November. After business was finished and exhibits discussed, Pres. Wilson invited Walter Weston to the platform for the purpose of giving an essay on *Boxwood*. Mr. Weston talked along the line of the care of *Boxwood* at the different seasons.

Cleaner Gardens—Well-Kept Lawns with Less Labor and Less Expense

Here it is. The light garden and lawn mower tractor you have been wishing for. Designed to do wheel hoe weeding and cultivating and instantly convertible into a tractor lawn mower. This outfit with one gallon of gasoline and a box to guide it will usually do more and better work than four men with push implements. Leading gardeners endorse the

BOLENS POWER HOE and Lawn Mower Tractor

The BOLENS is different. Investigate before you buy. Catalog on request.

GILSON MANUFACTURING COMPANY
215 Park St. Port Washington, Wis., U. S. A.

King GREENHOUSES

are built in sections or units 8'5" in length and from 9' to 32' in width. This makes possible the building of a greenhouse with a few sections and adding new sections or units each year or two until a complete range with, possibly, a palm house has been built. A good point to remember and suggest to your employer when he plans to build.

Catalog 52A which we shall be pleased to send to you, shows many designs and sizes all of which can be built complete or of sectional construction. Write for your copy today.

When you think of good greenhouses, think of King.

*The Insecticide that
kills plant Lice
of many species.*

The Insecticide of Recognized Merit for Greenhouse and Garden

APHINE is a concentrated material—mixes readily in water—efficient in its action—easily applied—free of the disagreeable odors and features of most insecticides—excellent as a wash for decorative plants.

FOR THE GARDEN—As a remedy against all sap sucking insects infesting flowers, fruits and vegetables, APHINE is most effective.

FOR THE GREENHOUSE

—Applied at regular intervals (once each week or ten days) APHINE will keep plants in the greenhouse and conservatory free of insect pests.

FUNGINE—For mildew, rust and other blights affecting flowers, fruits and vegetables.

VERMINE—For worms and insects infesting the soil.

Charles Carter, superintendent of the Dr.

Dr. J. C. Ayer's Estate, Glen Cove, L. I.

The Tribute of Charles Carter to Davey Tree Surgery

Glen Cove, L. I., Feb. 13, 1923

THE DAVEY TREE EXPERT CO., KENT, OHIO.

Dear Sirs:

I am writing to express my entire satisfaction of the work which your Company has done on the trees on the Dr. J. C. Ayer estate at Glen Cove, Long Island, over which I have charge.

I have only been with Dr. Ayer a short time, but I understand that you have served him satisfactorily over a period of years. Some of the surgical operations performed last year were very difficult, and a recent inspection proves that they are holding perfectly.

Dr. Ayer lost a number of very fine trees in a bad storm last season, but I feel that the work of your Company has made the remaining ones safe from future storms. Sincerely yours,

CHARLES CARTER

One of the trees on the Dr. J. C. Ayer Estate

To save the old trees from future storms, every gardener and estate superintendent needs highly skilled assistance. Many, like Mr. Carter, protect their trees by Davey Tree Surgery—a science developed by a generation of study and experience. A careful examination of your trees will be made by appointment.

A Choice Piece of Perpetual Summerland

Fortunately for you, its location is one that will exactly suit you.

As for size, it is neither too big nor too little, but one that just fits your requirements.

In an almost mystic way, this available bit of perpetual summerland is always flower-filled.

Sometimes it is filled with those lovely old-timey favorites of our Colonial days.

Then again, it is queenly roses and exquisite gardenias.

Or, if you like, literally dozens of sunny, sun-filled daffodils.

And, of course, violets, and orchids, with juicy peaches and thin-skinned succulent grapes, ripened months before the outdoor ones.

As for the cost of this piece of perpetual summerland, that is a detail that can be arranged entirely to your satisfaction.

At your suggestion, we will gladly call and talk it over, or if you prefer, will send you an *illustrative* piece of printed matter.

A Garden of Perennial Flowers

FIFTEEN BEAUTIFUL PERENNIALS

for **\$1.00** POSTPAID

This wonderful assortment includes the most showy perennials and will give a magnificent garden, besides yielding cut flowers bountifully throughout the spring, summer, and fall.

Perennials are easily grown from seed sown out in the open garden during May or June. They will give a gorgeous display of showy and handsome flowers that never fail to attract the flower-lover. Our collection contains one full size packet each of the following 15 handsome perennials:

ANCHUSA ITALICA—Magnificent spikes four feet tall, covered with rich blue flowers during June and July.

AQUILEGIA, LONG-SPURRED HYBRIDS—Graceful flowers in many colors blooming profusely during May and June.

ARABIS ALPINA—The dwarf plants are completely covered with thousands of pure white flowers.

PERENNIAL BABY'S BREATH (*Gypsophila paniculata*)—Tiny white flowers borne on slender stems. Blooms from July on.

CENTAUREA MONTANA—This hardy Cornflower has large, showy, thistle-like, blue flowers.

COREOPSIS GRANDIFLORA—A popular free-blooming perennial with large well-shaped flowers of a rich golden yellow. Blooms during spring and summer.

DELPHINIUM, CHOICE MIXED—Beautiful spikes in shades of blue and purple.

DIANTHUS PLUMARIUS—Star-like, rich rose flowers during June and July.

FOXGLOVE, FINE MIXED—Beautiful spikes in white, pink, rose, etc.

GAILLARDIA GRANDIFLORA—Large, yellow flowers marked with crimson.

GLOBE THISTLE—Thistle-like foliage; large ball-shaped flowers.

HOLLYHOCK DOUBLE MIXED—A complete mixture of fine colors.

LYCHNIS CHALCEDONICA (*Burning Star*)—Bright scarlet flowerheads.

PLUME POPPY—A stately border plant 8 feet tall.

SWEET WILLIAM, SINGLE MIXED—Blooms from July on in many bright colors.

These 15 packets of perennials if purchased separately would cost \$1.50. Plant your perennials during the month of June for next year's blooming. The collection will be mailed anywhere, postpaid, for **\$1.00**

Model "L"

COLDWELL LAWN MOWER

Six Acres Per Day—If Needed!

Perhaps you do not always find your lawn mower adequate to enable you to properly mow the lawn, and honor your daily schedule.

And that's where the Model "L", a Coldwell Mower, lends timely aid. This small mower of large capacity, mows and gently rolls the greensward in a manner that promotes most vigorous grass growth.

Close up to, and around shrubbery, or on clear stretches it functions with equal facility—six acres per day, yet a meagre appetite for gasoline.

The Fuller and Johnson motor in the Model "L" requires but scant attention, and operates the five keen blades with an abundance of power.

More on request from your dealer or from us.

Things and Thoughts of the Garden

WILLIAM N. CRAIG

THE coming of Daylight Saving or "Summer Time," as it is commonly termed in Great Britain, should be welcomed enthusiastically by every true garden lover. The only argument of much weight which I have heard advanced by gardeners or commercial flower growers against this measure is, that it is necessary to keep a man on duty at the greenhouses an hour longer to attend to the necessary watering and ventilation. This should be easily arranged on private estates, much more readily than the Sunday "duty." Of course, there are to be found objectors to this and every other man-made scheme by those who swear by what they piously term "God's Time" which was itself changed long before the introduction of Daylight Saving. Massachusetts, a great industrial state, holds fast to it and the opposition of agricultural interests has dwindled with the change from a seven to a five month Daylight Saving period. There is every reason why gardeners, and all garden owners and garden lovers should welcome the change; the long, pleasant evenings which can be spent in the garden, and the extra hour when many amateurs can till the soil in their little gardens should many times outweigh the need of keeping someone at the greenhouses a little longer. The old, familiar argument trotted out each season that men cannot be put to work because there is dew on the plants is all but obsolete. The gardener, or farmer, unable to find work for his assistants when vegetation is damp should get into another business. I have always considered Daylight Saving a great horticultural asset—many millions in America are enjoying it annually and some day I hope the opposition from agricultural interests will pass and that all of our citizens may enjoy it as they did during the war period.

* * *

At this season when the country is very beautiful, fields verdant, woodlands a perfect joy with the multiplicity of green hues on trees and shrubs, gardens and orchards rich with bloom, and song birds musical on every side, how saddening it is to notice so much of the beauty, peace, and repose of a landscape disfigured if not destroyed by these abominable billboards. At one time they were mainly along our railroads, but the advent of the automobile has changed all this. It is true that some legislatures have passed laws to deal with these commercial monstrosities, but these laws are as usual well punctured with loopholes and do not amount to very much. The National Association of Gardeners has on several occasions placed itself squarely on record against the repulsive, glaring bill-

boards flaunting along our highways and numbers of civic bodies are striving to free their respective communities from these nuisances, for surely billboards can scarce be classed as necessities. The levying of a heavy tax would no doubt reduce this crying evil. The billboards both disfigure and depreciate the value of property, for whatever violates the laws of harmony and beauty damages property values, and is a reflection on the good taste of the community. It is an excellent plan not to patronize firms which offend our eyes. Offenses to the ear and nose are restricted and often punishable, why not sights which offend our eyes?

Tulips are amongst the most popular flowers at present. The last few years have seen a steady decline in the popularity of the early blooming section, and a tremendously increased interest in the Darwins, Rembrandts, and May flowering varieties. These latter varieties are much more satisfactory for the amateur than the early type; they in nearly all cases grow taller and have a more stately appearance than the earlier, and while they flower somewhat later prove much more persistent and in numerous cases are very much better the second and third years if undisturbed. They do especially well in herbaceous borders, planted in clumps. It seems strange that in our parks, and public gardens hitherto so little use has been made of them. The general excuse advanced against their increased use is that as they bloom rather late, it delays the setting out of the regular Summer bedding. I am glad to note that many private estates now use this class of tulips entirely, both in mixed borders and in special beds, and I feel sure the general public would be willing to wait a few days longer for the more or less stereotyped arrangements of coleus, alternantheras, santolinas, alymphas, geraniums, cannas, and even scarlet salvias, which adorn most of our public grounds, and too many private gardens today.

Of the May flowering tulips out of a large number of varieties the following, which are all of very moderate price, have with me proven most satisfactory: the Fawn, rosy fawn in color, shaded blush, very graceful and of an unusual color; Golden Crown, yellow edged with red; Mrs. Moon, very deep yellow, with reflexed pointed petals; Picotee, a good old variety; Inglescombe Yellow, often called the "yellow Darwin" with large globular flowers; Gesneriana major, rich deep scarlet with a bluish black centre, a popular Memorial Day tulip in some of our more northerly states; Gesneriana lutea, a splendid

golden yellow, the foliage is much heavier than on the red variety; *Le Rêve*, sometimes called *Sarah Bernhardt*, of a striking rose buff color, very large flowers, one of the most admired of all tulips, not infrequently listed amongst the early tulips; the old *Bouton d'Or*, also called *Ida*, is a good pure golden yellow; *Ellen Willmott*, soft creamy yellow in color with an elongated flower and reflexed petals is a very pretty sort; *Inglescombe Pink*, a charming tulip, rose pink, shaded salmon in color. *Leghorn Bonnet* has always been a favorite with me, it is pale yellow in color and some catalogues list it under the name *elegans lutea pallida*. *W. T. Ware* is a glorious deep yellow, the flower is large and lasts wonderfully. *Golden Spire* has a very large reflexed flower, deep golden yellow in color and edged with orange scarlet. Of a rather unusual color is *Fairy Queen*. The shade is a rosy heliotrope, with a margin of amber yellow. Some good tulips are left out of the foregoing list but those named have all proved very satisfactory in New England. There is a rather overwhelming predominance of yellows in the May flowering tulip section.

* * *

Speaking of tulips, how few there are who grow the very interesting species. While some of these make good garden plants, the bulk are more at home in a rockery. *T. Greigii* is the largest and most showy of this group, the bright crimson scarlet flowers have a black blotched centre and the foliage is variegated, the blotchings being dark. The latest of all the species to flower is *T. Sprengeri* with scarlet flowers. *T. Sylvestris* with yellow flowers is occasionally found wild in England and is found over quite a wide area in continental Europe. I have found this variety succeeds very well naturalized in grass land where the soil is well drained, not too rich, and the grass does not grow too vigorously. It is a graceful species with yellow flowers. *T. Kaufmanniana* is a native of Turkestan and has been in commerce about 50 years. It is the earliest of all tulips to flower and has proved to be a persistent variety. One clump I have in mind in a rockery has flowered freely for ten years; the flowers are very variable in color but are generally white, tinted with carmine, the centre is yellow. *T. cornuta stenopetala*, also called *acuminata*, has some of the characteristics of *T. Gesneriana* and is a good grower with red and yellow flowers. At the late New York flower show there were one or two exhibits of *T. Clusiana*, the "Lady tulip." This variety stands gentle forcing and succeeds very nicely in six-inch pans. It is one of the very best sorts for the rockery; the flowers are pale yellow, striped with red, and are very fragrant. Everyone at all interested in tulips should plant a few of this pretty variety. The little *T. Lownei* will appeal to those who have a rockery; it only attains a height of three to four inches; its flowers are white in color, tinged outside with purplish pink. *T. Turkestanica*, native of the mountains of Central Siberia and the Caucasus, is really a robust form of *T. biflora*. It is either pale yellow or white inside the flower and tinged with green, red, or purple outside. One remarkable feature of this tulip is that it often carries four to six flowers to a scape. *T. Hageri* is another fine rockery variety; flowers are generally red in color and the stalks average six inches in height. *T. Retroflexa*, a supposed garden hybrid between *Gesneriana* and *acuminata*, is a quite lusty grower with yellow twisted flowers. *T. Præcox* has purplish flowers, is slender in habit and attains a height of 15-18 inches. The brilliant *T. linifolia* is a dwarf grower, this variety comes from Bokhara. *T. præstans*, another Bokharan species also carries several flowers per scape; the color is orange vermilion. The species aforementioned have done very well in the vicinity of Boston, Mass., there are other good sorts which might

be added but I have named enough to provide an interesting and well varied assortment for any reader of the *GARDENERS' CHRONICLE* who may wish to try them.

*

There can be no question but that the most admired tulip at both the Boston and New York Spring flower shows this year was *De Wet*, sometimes called *General De Wet* and also *Fireglow*; as forced it is a peculiarly rich and glowing orange in color. Grown in the open it is a lovely golden yellow, flushed with fiery orange scarlet, and a most distinct and unique shade. In a collection it at once rivets our attention to practically the exclusion of all others. This belongs to the early flowering class of tulips, but the plants grow taller than the average earlies, more nearly approximating the Darwins in height. *Pink Beauty* in the last few years has become one of the most popular of all bedding tulips; its deep glowing rose color, becoming fainter towards the edges, its excellent habit, and fine lasting qualities, commend it to all tulip lovers. I do not think there is any finer pure white bedder than white *Joost Von Vondel*, some catalogues carry this under the name of *Lady Boreel* and when they do not give the synonym, purchasers unacquainted with tulips, are likely to buy this for a new variety. In its own particular color, satiny rose, *Prosperine* remains without a peer; it is one of our finest bedding tulips. In scarlets *Sir Thomas Lipton* is extra brilliant, *Rising Sun* is a grand deep golden yellow and is a somewhat taller grower than the average. *Golden Queen* pleases many, does not grow so tall as *Lipton*, and carries a large globular flower.

* * *

The forsythias have been wonderfully fine this season. In spite of the prolonged Winter we fortunately had no very low temperatures, and the forsythias, in common with some other deciduous flowering shrubs, escaped injury to their flower buds. On sloping banks, the old *F. suspensa* is still quite useful, and *Fortune's Golden Bell* is by no means a back number, but *F. intermedia* is far better and there is a form of *intermedia* called *aurea* which has deep yellow flowers and yellowish foliage which may appeal to those who admire leaves which are other than green. There is also a golden variegated form of *Fortunei*. *F. viridissima* is an old variety blooming a little later than other sorts, the bark is deep green in color and the plant is of compact habit. For those wanting but one variety I would recommend *F. intermedia* and do not plant them three feet apart each way as do many landscape architects unless you will be prepared to remove nine-tenths of them within three years. Forsythias need lots of room and are robust growers.

* * *

Amongst the very desirable early flowering shrubs which are of quite dwarf habit and are therefore valuable in the small garden I do not know of one which is attaining a greater popularity than the Korean *Viburnum Carlesii*. A popular name the "Bouvardia shrub" has been given to it as the dense terminal cymes of blossoms which appear with the leaves somewhat resemble the heads on bouvardias, and have a most delightful fragrance, a fragrance reminiscent of *Daphne Mezereum*, the may-flower (*Epigæa repens*), and that finest of all bouvardias, *Humboldtii*. As this shrub is very shapely, does not exceed four to five feet in height, proves perfectly hardy, flowers freely each year, with flowers which are lasting as well as fragrant, and as several nurserymen now offer it at a moderate price, here is something which many owners of even quite small gardens might well plant. There are many good *Viburnums* which are invaluable in landscape plantings, but *V. Carlesii* is of more moderate habit than any others, and none can approach it in fragrance.

In the Garden and in the Greenhouse

GEORGE F. STEWART

GARDENING is like very few professions. It largely depends on how closely we can co-operate with the natural elements. These, however, often act in a very erratic manner, and are beyond our control, at least out of doors, to a very large extent.—Take the past Winter here in Massachusetts; it has been like no other one, within the memory of many of our oldest residents. We were in hopes of an early Spring, after the snow being so continuous from November on.

We argued thus: the ground has been so heavily covered with snow that the frost would not penetrate to any great depth, and with the lengthening day, and the sun getting stronger, when March arrived, we would have a sudden quick thaw, and in a few days the ground would be in condition for putting in early crops, at least as early as the second week in March. The result has been that that month has been one of the most frosty we have experienced, and with very high biting winds has, several nights, taxed out heating equipment to its utmost. Several nights some panes of glass, loosened by the long Winter, have been blown out in some unexpected corner, and disappointment has followed over some cherished plants which have been either marred, or completely ruined, by the cutting frosty wind blowing through that part of the greenhouse thus exposed, through no fault of those in charge. In fact, it may have happened when they thought they could safely retire, after watching through the worst part of the night, knowing that the heater was well able to take care of things for the few hours that were left.

Timing of the flowering season of certain plants has also been disappointing to some of us, owing to lack of sunshine at a season when we generally counted on clear skies. As we look over our outdoor plants we find many things that discourage us. We gave our plants their usual covering for this section of the country, and the result has been that together with the great depth of snow, it was too much, causing rot in quite a number of our border plants. Others, owing to the ground not being frozen at all, started into growth under the snow, and these have been destroyed, the late cold blasting winds nipping them in their soft condition. Mice have also done considerable damage, and I am convinced from some little observations, that the grey squirrel is about as destructive at barking certain bushes and trees, as the mouse. Gardening, looking at it from the standpoint of a visitor, and beholding a floral display at its best, is a most wonderful occupation, but very few realize the brain racking care, and many disappointments that very often the gardener has been through, before such a restful, satisfying picture has been produced.

Late May and early June generally find the gardener in the thick of the fight to produce seasonable flowers, fruits, and vegetables, and if we lay hold of opportunity at the right moment, we shall have a fair measure of success. Ideals no one can rob us of. Our enemies may try to mar them, but to the heroic soul they are still there, and worth striving for.

Do not neglect staking peas at the earliest opportunity, and when they are an inch or two over grown, if they look too thick in the row, thin them out a little. Better quality will be the result. I question in our climate, if it would be wise to trust growing peas spaced as widely as they do in Europe. From photos I have seen, they certainly have wonderful yields, as the result of planting widely.

We always, with a sowing of peas, plant spinach

between the rows as it runs so quickly to seed, it is generally used up before it interferes with that crop. New Zealand spinach is not a *Spinacia* at all, botanically belonging to *Tetragonia*. This plant is used widely as substitute for *Spinacia* during the hot months, and does better if started in small pots as it is a tropical subject. It will grow from seed sown out doors, but will produce leaves much later from the plants started indoors. We sow three seeds to a pot and plant three feet apart. It very soon closes up between the hills at that distance.

Sow dwarf and pole Lima beans, after the middle of May. Put in plenty of seed and thin out after they are well up. This class of bean is liable to rot, if after they are sown it should turn wet and cold for several days. Plant pumpkin and squash about the middle of May and later. These, as regards their seeds, act about the same as Lima beans in unfavorable weather.

Soft coal soot is an excellent dust put around young vegetable plants. Insect pests are not at all happy, if a good dusting is kept around them while they are in a small state. However, remember and do not get it mixed with lime, as a powerful ammonia will be the result, and the tender foliage will be burned. A sprinkling of any good vegetable fertilizer after a crop is well up may be given between the rows before hoeing or watering, keep it well away from the plants, as many chemical fertilizers burn not only the leaves, but the stems of the plants as well. The best safeguard is a good watering after an application.

Tomatoes may be planted out towards the end of May, also egg plants, but don't forget that they are quite tender, and should be well hardened off. Without a doubt the best fruit is obtained from tomatoes, if they are trained over a trellis, or tied singly to a stake. Also rub out all side growths, training to a single stem.

Good melons can be grown outdoors if the weather is normal. Last year we had so much wet weather that we did not get a good set of fruit. If one has a decent house available they are more easily handled indoors.

The orchard requires a good deal of work nowadays, with so many fungous, and insect pests. Spraying or dusting has to be done several times to insure good fruit. The dealers have these preparations always in stock, and can be relied on as regards ingredients, if brought from a reputable firm. Dusting on the whole is considered by some more expensive than spraying, but it can be done much more quickly. Get busy as soon as the flower petals begin to fall from the trees, and look out for later hatchings of moths. A spraying with arsenate of lead will generally take care of the currant worm, on the smaller bushes, but dusting will do here also, if coloring of the foliage is an objection. Fruit of all kinds requires much attention to produce first-class specimens and good keeping quality.

In the flower garden from the middle of May onward there will be successions and changing scenes of color. The Darwin and May flowering tulips are among the most interesting, and when planted in clumps of ten or a dozen between the herbaceous plants, the green foliage, in its several shades, of these perennial plants, softens the brighter colors, and forms a pleasing combination. Without bulbs, the herbaceous borders in the Spring would give us a long period of very little flowering material, and would be of very little interest, except to plant experts, who are always enthusiastic when watching all stages of growth. Darwins, and other late flowering tu-

lips, last as a rule several years without any disturbance. However, as they flower, their general appearance should be noted, and if there are any signs of deterioration, the clump should be marked, and after the flowers begin to fade, lifted, and replaced next Fall with new bulbs.

Many flowering shrubs will be in their glory this month, and as soon as the flowers drop, one should look over the bushes, and remove as much of the old wood as will not interfere too much with the shape of the plant. Every chance should be given for any young growths to develop. Any plants that are standing out by themselves may have been allowed to ramble into growth forming old gnarled branches. The time arrives when they have to be dealt with and a severe cutting back is the only remedy. They may look a little bare for a season, but there is generally plenty of young wood near the centre which, when given a chance to develop, will soon take the place of what has been cut away. Dig around the plant at the same time, applying plenty of plant food suitable to it.

Rhododendrons have wintered very badly with us. The plantation here was about fifty years old, planted originally in peat with a little mixture of an upland loam, red in color. This loam, from my observation, seems ideal for shrub growing, especially for our native ones. The rhododendrons, I believe, were badly damaged in the ice storm in the Fall of 1921, as they were then flattened right out on the ground. Although they apparently recovered their shape and outline, now there are quite large pieces burned quite red, especially near the top of some of the plants, some of which were fifteen feet high. Give the damaged parts a chance, and if they show signs of breaking into growth lower down the stems, cut them back immediately above these young shoots, and they may in time fill in again. However, rhododendrons are never a sure thing near Boston.

The more hardy bedding plants may now be planted out about the middle of May. The tender sorts are better to be kept in the frames until the first week in June. Although one may not expect frost, yet coleus are affected by a raw wind when they are first set out, if the weather is inclined that way.

Look out for leaf rollers and other insect pests on the rose bushes. The dry dust composition is one of the most up-to-date remedies for many of these enemies of the rose, the leaves being more easily washed clean when roses are to be cut. And the rose bugs, well! they are yet with us, is about all that can be said, and the best remedy is, *catch them*.

Keep an eye on all plants in the flower garden that need staking. This is an art, and we have never yet seen a real good stake for this purpose, there are very few who can do this very necessary work, and preserve the natural shape of the plant.

A last sowing of annual asters (American branching) may be made the first week in June. These, if planted on good rich, new land, will give flowers very late. The early frosts do not seem to hurt them much, and we find that along with gladioli they are among the best of our late cut flowers.

Keep the hoe going whenever time permits. It is better than an application of fertilizer, if done often enough. A neat, well kept place depends a great deal on how well the walks and lawns are kept in fit condition. Mow the lawns twice a week, if one can afford the labor, and the walks should be edged and raked, at least once, in that space of time.

The greenhouses, in a way, need very watchful care at this season. Draughts are not easily avoided, owing to the prevalence of the east wind, which at this season,

is apt to spring up any minute in this section of the country. Spring potted plants of the hardwood nature need careful watering. The new compost may not yet be netted with roots from the old ball, and care should be exercised that that part of the root does not get quite dry, before the outer part, near the outside of the pot. All these details determines if your specimens are to make a nice even thrifty growth. Look the plants over several times this month, and any exceptionally strong shoot may be given another pinch. If this is not done, a few strong growths, allowed to grow at will, are very apt to spoil the shape and symmetry of the plant, besides weakening the other shoots.

Camellias are again growing freely; examine the drainage, making sure that water has a free outlet as a stagnant condition is certain death to them. It is not safe to use Hydrocyanic gas on the young growth, and other means must be employed to keep plants clean during the Summer. We use Barrie's soap sprayer, a most useful instrument, when filled with soap and attached to the faucet with a good nozzle on the end of the hose. We give them a thorough good syringing, when they need water. It not only keeps insects in check but it also loosens the black smut that is very likely to collect on the leaves of old plants. Feed the plants lightly if they have not been repotted. We find they respond to Clay's Fertilizer, weak cow manure water and Scotch soot, if not overdone.

If late shrubby calceolarias are wanted, pick off all the flower buds that are showing, and give them a cool shady position. Feed them liberally, until they show color quite prominently. By doing this, we have had fine plants in July, only they did not last as long in flower as earlier in the season.

About the end of May, Bouvardias for Fall flowering may be planted outdoors. However, much better results may be had, if one has a bench indoors for them. One can pinch them later than outdoors, timing them to come in after the chrysanthemums. If kept clean and fed well, after the bench is full of roots, better flowers than on the outdoor grown plants, will be produced.

We do not grow exhibition chrysanthemums and we never plan to have them rooted earlier than the first of June. We grow four plants to a seven inch pot, running them up by disbudding in the usual way for single stem flowers, until they are about four feet high, then we let all the buds and shoots develop naturally. These plants we use for cut sprays, and also as pot plants in very high windows, in which position they are very decorative. Rooted so late, if not overcrowded, the foliage is retained well down to the pot. Of course, as regards plant food, and other conditions of culture, we treat them as well as we know how, under our conditions. In the years now behind us, when growing exhibition plants, we always liked to have them in their final pots by the first of June. Single stems for the same purpose we potted at the same time. We have always contended that better flowers were grown in pots. However, a very fine grower whose son now stands high in our N. G. Association once told me, that he grew his blooms planted out on a shallow bench, and he said furthermore, that he himself planted them out of four inch pots on the fourth of July, when the boys were away having a good time. At any rate he produced the flowers, when the great day of competition arrived.

Boronia elatior flowers with us in a cool house, somewhat shaded during the last of May; the variety pinnata is the best if it can be obtained. Pimelea decussata flowers about the same time. I wish I knew where to get the variety spectabilis; as it is, in my opinion, the best hardwood plants are now sadly neglected. I do hope some one will make a hobby of them one of these days, as

there are so many gems which we often long to see. They are also very decorative and last well as cut flowers.

In the tropical house the principal thing from now on is to encourage an even, steady growth. If it is not possible to give the flowering section a house by itself during the Summer, the part of the house that it is possible to shade the least, should be used. I have seen bigger and better specimens than ever I have seen in the British Isles, and they were given a much more airy atmosphere to grow in, than was the rule there. As soon as the thermometer goes over 60 degrees outdoors, give them abundance of air. By doing so they dry out much more often, and may be given more plant food. A better and firmer growth will result, which is essential if they are to be used in decorative work. Of course, the floors, and between the plants on the benches, need damping down as the foliage section requires a moist atmosphere when making its growth. Gorgeous flowering display can be had during the Summer by growing such plants as Allamandas, Clerodendrons, Anthuriums, Dipladenias, Eucharis, Exoras, Pancratium, Franciscea, Medinilla, Stephanotis, Vinca rosea, etc. Insect pests of all kinds must be kept in check. Red spider is one of the worst, as if, perchance in some corner they get a foothold, a very short time of neglect will ruin the appearance of any plant. Syringing will not do the work, unless they are washed clean off the plant, but there are many contact insecticides that will, if applied thoroughly.

Cattleya Schroederæ will now have passed out of flower; just before they have started their new growths, the condition of the compost they are potted in should be examined and any of it removed that may be loose on the surface, replacing it by fresh material. As from my observation of orchids, they are all benefited by a resurfacing once a year, provided one does not break the roots in the operation. Of course, any that are over the sides of the receptacle will need repotting. It is also beneficial to remove any of the pseudobulbs that have lost their leaves. Orchids of the Cattleya family are now so much cross-bred that they flower at all seasons, and potting is not now confined to certain seasons as it was thirty odd years ago. These crosses are like many other plants that have been crossbred, many of them are not the equals of good types of their parents. Over some slight change in markings and structure of the flower, an enthusiast gets a little worked up, but to many, they create little interest. The best thing in my opinion in cross bred orchids is the filling in of the gaps that used to be at certain seasons, so that a continuous supply of flowers may now be had the year round. I can be as enthusiastic as anyone when I see a real outstanding flower or spike, but there is a tendency in all such work to be freaky.

Dendrobiums need to be watched as the young growths in their early stages are easily lost, if climatic conditions are not quite right. A draughty chill with too much moisture will do it, as also will a hot stuffy, humid atmosphere. There is no question in my mind, but what all orchids in their growing season require plant food. The question is what, and the strength of the food given. The so called natural manures, when applied often and weak in quality, I have proved to my satisfaction to be beneficial. It may be given in the compost, or by evaporation. As to which is the better method, I have not yet decided convictions, having no time at present to experiment.

Grapes that have come along without any forcing are somewhat later with us this season. The varieties that are shy setters should not have their bunches thinned down too early. We find, if they are properly supplied with food, it does them no harm to let all but the weak small ones hang, until bunches with a fairly even set

are secured. We are not very particular about an equal space between each one on the rod, if they are anywhere near right. Good fruit is the main thing to have in view. The early house will be approaching the ripening stage, and requires plenty of fresh air to finish.

Pot fruit needs close watching to avoid dryness, and they also have to be fed more liberally than trees planted in a border. Avoid over cropping on forced peaches and Nectarines, saving the fruits that turn toward the light.

THE HERB GARDEN

IN most gardens the herbs which are in demand for culinary purposes are grown in a quarter of the kitchen garden, and this quarter is a very interesting and useful one; but a herb garden proper as an adjunct to the flower garden may be made a most delightful and attractive feature, and if a position can be chosen between the kitchen garden and flower garden it would be very appropriate.

There is a fascination about herbs, for they seem to carry us back to the time when gardening was first attempted seriously in this country, and it is not too much to say that from the old herb gardens have developed the beautiful gardens of flowers, shrubs, trees, and other ornamental plants of today. Herbs include some of the sweetest smelling plants of the garden, and for that reason alone they are worthy of being grown.

Any ordinary garden soil suits most herbs, although, naturally, the same soil will not suit all equally well; but with a little forethought in supplying individual requirements, quite a large collection of herbs may be made to flourish in one garden.

If the site is clear of large trees, the aspect is not a matter of great importance, but it is essential that plenty of sunshine and air should reach the plants, without which they would grow feebly and much fragrance would be lacking. The shelter of an existing wall or hedge is an advantage.

The size and shape of the garden must necessarily be governed by circumstances, and these will affect the scheme of design; but, whatever the size and shape, a good plan is to enclose open sides with hedges.

The Moss Rose, the Damask Rose, Sweet Briar and Rosemary are good subjects for this purpose, and quite in keeping with the scheme. Having defined the boundary, a narrow border may be retained on the perimeter, with a 2 ft. path inside it, thus dividing the garden into a continuous, encircling border with a central block. Transverse paths in each direction may be laid through the centre, and, if space permits, further paths in each direction at equal distances from the centre to the outside border, thus dividing the central part into sixteen beds.

The arrangement of the herbs may be left to individual taste, but each of the following subjects is worthy of a single bed: Spearmint, Peppermint, Catmint, Woolly Mint, Alecost, Balm, Horehound, Marjoram, Sage, Common Thyme, Lemon Thyme, Lavender, Hyssop, Summer Savory, Winter Savory, Tarragon. For the borders, such dwarf-growing subjects as Chives, Fumitory, Pennyroyal, Prunella, Saffron, Woodruff, Parsley and Chervil might be planted as an edge, with groups of Alkanet, Angelica, Anise, Basil, Borage, Burnet, Camomile, Caraway, Coriander, Cotton Lavender, Dill, Elecampane, Fennel, Mallow, Marigold, Purslane, Rue, Southernwood, Sweet Cicely, Valerian and Wormwood.

Many of these plants are annuals or biennials, and may easily be raised from seeds. The perennials may be increased by division or cuttings. It is best to divide the plants in the early Autumn; but strong plants from cuttings may be set out at any time when the weather is favorable.—*The Gardeners' Chronicle* (British).

What Is a Plant?

WILLARD N. CLUTE

IT is a good deal easier to define a plant in general terms than it is to get down to particulars. It is, of course, recognized by everybody that plants form one of the two great divisions of living things and that animals form the other, but the difficulty occurs when one begins to lay down rules that will absolutely distinguish one from the other. Anybody can tell a cow from a cabbage but nobody feels very confident that he can always distinguish between the animal and the plant when both are formed of a single cell. Even the text-books are not always clear in such matters and both zoology and botany have often claimed the same organism for their own. The difficulty of exactly defining a plant is complicated by the behavior of the fungi and other parasitic plants which, in their methods of assimilation, at least, are more like animals than plants.

In one of our scientific journals, botanists have recently been amusing themselves in trying to make a definition that will fit all cases but without any very great success. The dictionary definitions are unsatisfactory in that they all include too much or too little. The statement that a plant is "an organized non-sentient being endowed with vegetable as distinguished from animal life" means nothing unless one also has a definition of what "vegetable life" is. Another dictionary definition says that a plant is "a vegetable product nourished by gases and liquids and not ingesting solid particles of food." This is also faulty, for as far as use is concerned, plants also make use of solid particles, digesting them just as animals do, and later oxidizing them by a process that is practically identical with that of animals.

A substitute suggested by one writer is that a plant "is an organism possessing chlorophyll or descended from chlorophyll possessing ancestors." Another is that a plant is "a living thing which manufactures its food from the raw materials of earth and air, or one whose ancestors did so." Were it not for the fungi and other colorless plants, one might at least distinguish the plants from the animals by the statement that "plants are living organisms that unite various lifeless substances by the energy from sunlight while animals incapable of doing this, secure their energy by tearing down what the plants build up."

Any of these definitions will answer for ordinary cases and we may let the technical botanist argue about the exceptions. There is, however, another phase of the subject which offers perhaps still greater opportunities for discussion. Assuming that we can always distinguish a plant from other living things we are still confronted by the problem of how much of a vegetable complex is a plant. The question is not so difficult in the case of annual plants for one sows a seed and from it there comes up a form that grows to maturity, reproduces, declines to old age and finally dies. This, indeed, is a plant. When it dies, it may leave behind it a million descendants each, in time, duplicating the life cycle of its parents and each capable of being distinguished from its fellows. But what about the case when one plants the seed of the wild plum or the white poplar? After a time we have not a single distinct organism but a tangle of forms produced from root-sprouts. Is this all one plant, or a group of plants? The banyan reverses this process and produces roots from the branches and gradually spreads over enough territory to shelter an army. We speak of it as a banyan tree, but it is not a tree in the sense that a pine tree is a tree.

In the strawberry, we find certain branches that are

manifestly for the purpose of producing new plants and the same is true of the "hen-and-chickens" and the strawberry geranium, which is neither a geranium nor a strawberry. These new plants, however, are not quite in the same category as those produced from seeds, for they are still attached to the mother plant. The mangrove has devised an improvement on this method. Its fruits do not separate from the parent plant when ripe but continue on until the plantlets they contain have grown to a considerable size. Then they fall from the tree ready to start in life for themselves.

Among the lilies and "top onions" we find bulbs and bulbets that drop off and produce new plants as distinct as their parents, and we have no difficulty in distinguishing between the separate individuals, but there are other lilyworts whose methods of reproduction leave us in more uncertainty. The adder's-tongue or dog-tooth violet, for instance, begins as a seedling and forms a bulb at the end of its first year. The next year, however, this bulb may send out one or more slender subterranean stems called "droppers," which wander about in the earth and finally produce new bulbs at their tips. At the end of the second season the original bulb has disappeared but there are several new bulbs scattered through the soil. Are these separate plants, or a widely distributed single plant?

There is a long list of plants such as irises, blood-root, and Solomon's-seals whose subterranean stems branch and branch again, forming a clump of considerable size. How much of this clump shall we call a single plant? Commonly, such forms spread out from the center in all directions, forming a circle which is commonly known as a "fairy ring." Such fairy rings were first known in the fungi and named because it was supposed that the fairies danced in them of moonlight nights, but now many other plants are known which form similar figures. When the old branches decay and disappear the branch-tips are left as separate individuals. Thus time alone may make several plants out of one!

When man takes to multiplying plants he adds to the confusion by making separate plants from pieces of another. When he finds a form of value he may multiply it excessively in this way. All the Concord grapes, for instance, are but parts of one original vine. In a certain sense there is only one Concord grape vine in America; in another there are millions. The same is true of the Navel orange, the Delicious apple and a host of others.

Most puzzling of all are the lichens, which may be described as the only living things in the world which are entirely vegetable without being plants. Although they have a definite shape, color, size and place of growth, and are comparable to plants in these respects, they are in reality plant partnerships in which an alga and a lichen are combined. For a long time they were regarded as true plants and classed accordingly, but now they have no standing as separate species. Whether they should be classed as fungi or algae does not concern us at present; the interest in them lies in the complications they introduce into the definition of what a plant really is.

All nature is but art, unknown to thee;
All chance, direction, which thou canst not see;
All discord, harmony, not understood;
All partial evil, universal good;
And spite of pride, in erring reason's spite,
One truth is clear, whatever is, is right.—*Pope*.

Some Hardy Geraniums In An Old World Garden

ARTHUR T. JOHNSON, F.R.H.S.

IN dealing with a genus so rich in species and varieties as that to which the Geraniums, or Cranesbills belong, one has of necessity to omit many worthy kinds. But those which I refer to below comprise a list of species which in this country at any rate have proved their merit under a wide variety of conditions. They are the "pick of the basket" in so far as color and form are concerned

Geranium ibericum

and are perfectly hardy, easy-tempered and reliable plants.

Perhaps the most gorgeous of these hardy Geraniums is *G. arvense* (*G. psilostemon* of Knuth), an herbaceous species which will go up to three feet in height and cover a dozen square feet with its noble foliage and heavy clusters of flowers. The tint of magenta which creeps into the brilliant crimson of these splendid blossoms may be counted an undesirable feature by some, but to my mind the jet black of the eye and veining of the velvety flowers is just sufficient to counteract any harshness that there may be in their sumptuous color. This is a plant to grow at the edge of the shrubbery, or woodland, or as a specimen on the lawn where, backed by an amplitude of green, it will be enjoyed to the fullest advantage.

In some respects *G. anemonæfolium* is a more refined species than the above. Though it has been in cultivation for many years it is still uncommon, possibly because it, being a native of Madeira, is not as hardy as most of its kindred. It has the habit of leafing during the Winter and Spring months which renders it liable to be cut by frost. Nevertheless, I am constrained to include *G. anemonæfolium* here since it has withstood 20 degrees of frost with the protection of a little dry fern and because it is generally such an easy doer in most soils. The broad and fleshy leaves of this species rise on stiff, straight stems from a short, woody stock to the height of some two feet. They are deeply cut and a rich, glossy green, and clear above them in the early Summer appear the flowering stems. These also are peculiarly rigid and, like those of the leaves, covered with iridescent hairs. The flowers that are borne in pairs at the many-branched ends of these stems are of an exquisite satiny rose-pink, the central eye and conspicuous stamens being a vivid blood crimson. This fine Geranium will maintain a succession of blossom throughout the Summer.

Here it sets seed freely, the seedlings are easily raised and invariably come true. A moderately cool position with shelter from the midday sun is most suitable for *G. anemonæfolium* and the choicest place in the garden is not too good for a plant of such undeniable merit. It should hardly be necessary to add that this noble plant must not be confused with *G. Lowii*, an error into which even the Kew Hand List once fell. The latter is a biennial, whereas the Madeiran plant is a true perennial. *G. Lowii* is, moreover, more like an overgrown Herb Robert than anything else and wholly unlike *anemonæfolium* in every way.

Another member of the genus which likes shade—cooler conditions, indeed, than any other—is *G. wallichianum*. This is a trailer which will cover nearly a square yard with its red-hued stems and grey-green leaves and bears an abundance of broad, saucer-shaped flowers from July to November. In the old type these blooms are a low-toned purple, but a much better, exceedingly beautiful form and one that is now entirely superseding the former is that known as Buxton's Variety in which the flowers are a lovely Nemophila blue with a large central zone of pure white. This species is quite hardy anywhere in this country and one that dies back to the base in the Fall.

Our native *G. sanguineum* which makes a rounded mass of tangled stems and deeply-cut leaves about ten inches high, bearing large flowers in a bold crimson, must always be included among the best of the hardy Geraniums. This is one of the easiest to manage, it is fond of lime and a warm sunny spot in poor soil. Of the many varieties of this species *G. nepalense* may be described as a magnified edition of the type (though its name actually belongs to another) and then there is the very charming pure white one which is so much larger in all its parts than *G. sanguineum* itself that some class it as a sub-species. Nor can one omit the dainty little *G. s. var. lancastriense*, which has a dense, prostrate habit and pretty salmon-rose blossoms—a gem for the rock-garden and as easy-tempered as it is pretty.

G. nodosum, again, bears some resemblance to the last-named in habit, making a mat of finely-cut, greyish green foliage which it adorns with flowers of a cheerful crimson. Like *sanguineum* this species seeds freely about our dry, hot banks and, not content with that, the two intermarry without restraint and people the garden with their hybrid offspring in every conceivable shade between a low-toned purple and a blazing crimson. Another couple which insist on hybridising, and which are even more successful colonists, are *G. endressi* and *striatum*. The former bears flowers of a strong pink, resembling the color of a raspberry ice, and those of the latter are scribbled with a network of fine rose and white veinings. Between them, these manage to raise an innumerable family of youngsters which, in the interests of domestic peace, bear an equal resemblance to each parent.

G. grandiflorum has perhaps the largest flowers of all its kind, an excellent species of about one foot high, spreading slowly by root-stems, and bearing throughout the Summer big, nodding cups of an intense ultramarine blue. Somewhat taller and more compact in habit is the fine old silky-leaved *G. ibericum* with its bunches of large blue-purple blossoms and gorgeous autumnal leaf color. *G. platypetalum*, once considered a form of the

(Continued on page 123)

Interesting Spring-Flowering Bulbous Plants

IT is astonishing what a wealth of garden beauty is practically unknown to the great majority of garden owners. Granted that a very large proportion of plant-lovers have very small—too small—gardens, it is none the less remarkable that there is such a comparative scarcity of many interesting species and even genera in private places. This is as true of spring-flowering bulbous plants as of any section of hardy plants. Daffodils, florists' Tulips, Hyacinths and Dutch Crocuses are to be found in practically every garden, but when we come to the very beautiful and interesting little Daffodils of the Hoop-Petticoat, Angels' Tears and cyclamineus sections, to mention but three, in how many gardens can we find them?

How often does one see even the commonest of the species Tulips growing, or species Crocuses for that matter? All the Fritillarias and Erythroniums are really uncommon. There must be many thousands of gardens of some size in which even our beautiful native Snakeshead, *Fritillaria Meleagris*, is wanting, and the same may be said even of the common Dog's Tooth Violet, *Erythronium Denscanis*. The glorious sky blue *Muscari Heavenly Blue* is still a catalogue name to many, and even the old Grape Hyacinth, *Muscari botryoides*, which was fairly common in Victorian days, is now almost a rarity.

Of the small *Narcissi*, none is more interesting than the forms of the Hoop Petticoat *Narcissus*, *N. Bulbocodium*.

Besides the *Bulbocodiums* and the Angels' Tears, there are such tiny and beautiful species as *N. minimus*, a perfect little trumpet Daffodil which scarcely exceeds three inches in height. This little charmer does admirably in the heath garden, or, in peaty soil, it will flourish on a rocky bank. *N. nanus* is a giant by comparison with the last, yet it scarcely ever grows taller than six inches. The blossoms are a deep golden yellow, and it is very effective among short grass on banks or mounds.

Of Tulip species none is easier or more beautiful than *T. Kaufmanniana*, an April-flowering kind of very variable coloring, but, as generally sold, soft creamy yellow tinged on the exterior with pink. *T. Greigi*, also April-flowering, is also fairly easy, though it seldom increases to any extent. This is a large-flowered species with brilliant vermilion blossoms; the leaves are handsomely blotched with purplish brown.

The wild species which is the parent of the May-flowering Darwin Tulips, *T. Gesneriana*, is admirable. It is, as might be expected, a tall grower, and the brilliant crimson-scarlet blossoms, each with a conspicuous black zone at the base, are sweet scented. *T. dasystemon* is a pretty little species very distinct from any of the florists' Tulips in that it habitually bears several flowers on a stem; strong bulbs will produce as many as seven. The blossoms, in their garb of yellow edged with white, remind one of that brilliant Californian annual, *Limnanthes Douglasii*. *T. persica* also bears two or more blossoms on each stem. This is a dwarf species, and the bright yellow flowers, which are bronzed externally, are fragrant. It is best, therefore, in the rock garden and not too far from the eye. *Tulipa sylvestris* is a native of Britain and worth growing for its fragrance alone. In color it is pale yellow, touched at the edges with red. There are a great number of other Tulip species, but these should suffice for the beginner to try.

When we come to the Crocus species, considerable selection is necessary, for an article could easily be written upon this topic alone. *Crocus Sieberi* is a Grecian species of bright lilac coloring in the typical form, with orange

at the base; but the natural variety, *versicolor*, has a wider range of coloring—white, purple and lilac being mottled and striped above the orange base. *Crocus Imperati* is one of the largest of the species Crocuses, yet, if size be a desideratum, it falls short of the Giant Dutch sorts. There is a beautiful clear rose form and also a pure white. This is quite one of the best of the very early-flowering species. *Crocus Tommasianus* is one of the most beautiful and useful. It flowers just before *C. vernus* and the Dutch varieties raised from that species. There are numbers of other spring-flowering species and several good autumn-flowering ones, all easy to grow and beautiful. Of these latter, probably, *C. speciosus*, of rich bluish purple hue with a touch of gallant orange provided by the stigmata, is the best.

Fritillaria Meleagris, the Snakeshead, still to be found wild in some English meadows, is equally easy in turf-land or in garden soil. It does not like too hot a situation, but will grow and increase on banks facing east or west, and does not disdain the light shade of deciduous trees. It will flourish on light sandy soils, but probably prefers a moderately greasy loam. When the quaintly speckled bells reach a height of two feet or more, as they will easily do when happy, this is a most effective plant. It is also excellent for cut flowers. There are now quite a number of named varieties, but those who have never grown the Snakeshead would be well advised to try the typical plant and its even commoner white (or whitish) variety first. Afterwards, stock can be rapidly increased from the seeds which are produced in such abundance. Of the other Fritillarias we may neglect the Crown Imperials (*F. Imperialis*), since everyone knows them, though, strangely enough, they are little grown nowadays.

Comparatively few gardeners have any conception of the beauty of the better Erythroniums when naturalized, for in suitable soils and situations naturalize themselves they all will. Perhaps *E. revolutum* is the most useful species. Some of the forms of this are magnificent and easy to grow. *White Beauty* has self-colored flowers of a delightful buttery-cream tone with all the finish we expect in the lily family. The blossoms are not seldom three inches across and when established the flower stems are often more than a foot in height. No one who has only seen this plant as a pigmy specimen in a small pot at a Royal Horticultural Society's meeting can form any conception of its beauty in the garden. This, indeed, applies to all the American species and varieties. Other good forms of *E. revolutum* are *Johnsoni*, clear pink, and *Watsoni*, cream color with a rosy zone. *E. Pink Beauty* is a fine rosy pink sort which makes an excellent companion to *White Beauty*, but is obviously not very closely related. *E. americanum* is a pretty clear yellow species with red spots, but not free to flower. The soft orange and yellow *E. Howelli*, rather a rare plant at present, is more floriferous. *The Garden*.

The whole life of man is but a point of time; let us enjoy it, therefore while it lasts, and not spend it to no purpose. *Platerch*.

A CORRECTION

In the April issue, the illustration of *Brasso-Cattleya*, *Ilene*, was inadvertently placed up side down, after it had slipped from the forms when ready for press. The error was not discovered till the pages were printed.

Stimulating Plant Growth With Carbon Dioxide

DR. E. BADE

THE introduction of carbon dioxide gas to plants inclosed in glass vessels to stimulate growth is quite old, but no success was ever derived from such a process, the plant invariably becoming abnormal. Such experiments have been carried out since the 18th century when Lavoisier discovered that the process of respiration in plants was analogous to the process of combustion and when Ingenhous proved that plants could revivify the most stagnant air in a few hours of sunlight.

More recent investigations have conclusively proven that plants breathe just like animals, that is, they take up oxygen and give off carbon dioxide. This process, which takes place both day and night, is most noticeable at the latter period. In the day time, while manufacturing starch in the leaves with carbon dioxide, taken in as a gas through tiny leaf openings, the stomata, and water, taken up through the roots, oxygen is given off as a waste or by-product, but normal respiration still takes place in spite of this fact although the gas taken up in breathing is nowhere nearly as much in quantity as that which is

plants not only growing faster, but more luxuriantly as well. This process is essentially nothing more than feeding the plant through the leaf by providing the raw materials necessary for the manufacture of its structure, a process of "fertilization" comparatively inexpensive, and distinctly new.

In the experimental plant of the "Riedel Fertilizing Process Company" of Elizabeth, N. J., this process has

Colocasia gassed. Not gassed

been tested for its practical value. Two exactly similar greenhouses of the usual type were built, but one was provided for the distribution of carbon dioxide gas, the other was used as a control house. The results obtained are exceptional. The gassed plants are thick, more massive, robust, vigorous, and healthy in every way, while the same plants in the control house which were not pro-

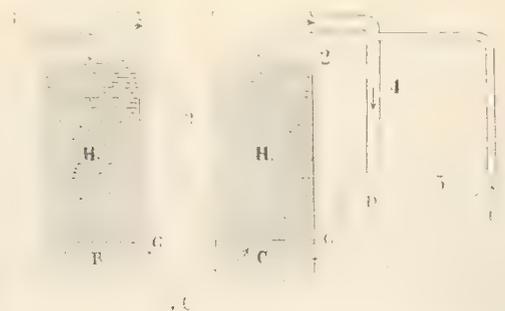

Diagram showing distribution of carbon dioxide

given off. This significant fact was only too seldom taken into consideration in former times while conducting gas experiments with plants, it being the source of the greatest errors.

Today it has been established that starch is manufactured with the aid of chlorophyll, the green coloring matter of the leaves which act like a catalyst.

1— H_2O (water) + CO_2 (carbon dioxide) = H_2CO_3 (Carbonic acid).

2— $2\text{H}_2\text{CO}_3 = 2\text{CH}_2\text{O}_2$ (formic acid) + O_2 (oxygen).

3— $2\text{CH}_2\text{O}_2 = 2\text{CH}_2\text{O}$ (formaldehyde) + O_2 .

4— $6\text{CH}_2\text{O} = \text{C}_6\text{H}_{12}\text{O}_6$ (grape sugar).

5— $\text{C}_6\text{H}_{12}\text{O}_6 = \text{C}_6\text{H}_{10}\text{O}_5$ (starch) + H_2O (water).

The water and the carbon dioxide come together in the leaf, and, under the influence of chlorophyll, carbonic acid is produced. But this reaction only occurs under the chemical influence of light rays, it does not take place at night. From the carbonic acid, formic acid is produced, which in turn is changed into formaldehyde. Each of these last two reactions produce a by-product which escapes through the stomata, it is oxygen gas. Six molecules of the formaldehyde are condensed whereby grape fruit sugar is formed. This, by a process of polymerization, is changed to starch, water being extracted by this transformation.

Slightly increasing the quantity of carbon dioxide available for plant food, has given remarkable results. The subjection of growing plants to doses of this gas at

Croton gassed. Not gassed

vided with artificial gas-nourishment, are small, more or less straggly when compared to the others, develop fewer leaves, and their root system is longer, less compact and dense.

The gas is produced by the furnace used to heat the greenhouse. When the house is to be gassed, which is only necessary at intervals, the short length of pipe leading to the flue, is closed, and the gas led through pipe A to the first scrubber. Two of these stand just outside of the house. The gas, which enters at the bottom, passes over coke H placed upon a grate G. From pipe I a fine spray of water is passed over the coke, the waste water

(Continued on page 124)

JELLY FROM WILD FRUITS

IN nearly every community there go to waste each year quantities of wild fruit suitable for jelly making, that might be had for the asking. Wild apples, wild plums, wild cherries, japauese quinces, hawthorns, wild grapes, cornelian cherries, barberries, and elderberries all make good jelly. Some of these can be used alone, while some are best when combined with other fruits. A mixture of wild apples and hawthorns, with a sprinkling of wild grapes, wild plums and elderberries gives a beautiful rose-purple jelly of excellent flavor.

The cultivated apple has been naturalized in many parts of the country, particularly in New England and New York, where it is commonly found along roadsides and country lanes. Landowners will usually give permission to pick the fruit, and though usually gnarled and sour, it makes excellent jelly. *Pyrus ioensis* and *Pyrus coronaria*, our native American apples, are common around St. Louis. Their small, yellow fruit is sour and somewhat astringent, yet it makes delicious jelly, particularly when used in combination with the large-fruited hawthorns.

The common elderberry, *Sambucus canadensis*, with its broad panicles of white flowers followed by deep purple fruit, is a familiar sight in eastern North America, and the fruit is commonly used in small quantities for wine and pie making. Combined with wild plums and wild apples it makes delicious jelly, while the addition of a few heads of elderberries will give crabapple jelly a beautiful rose-purple color without appreciably changing the flavor.

Most of the native plums make good jam and jelly. Several of the better forms have been introduced into cultivation and are the more valuable since they will succeed in regions where no other fruit will grow. The common barberry, now outlawed in the West because of its relation to the wheat rust, is still cultivated in many parts of the country and has run wild in the East. In combination with other fruits it gives a good color and flavor to jellies, and when used alone it produces a clear red jelly quite like that made from red currants.

The several species of wild grapes native to North America are excellent for jelly making, some of them being superior to the cultivated one in this respect. Though they are not as often neglected as many of the other wild fruits, large quantities go to waste every year, even in thickly settled regions. Good grape juice can be made from the juicier kinds, but it is apt to have a "stemmy" taste and seldom equals that made from the cultivated varieties. Fence-rows, riverbanks, and the edges of wood lots are likely places to find the vines.

Many different species of hawthorns are found in Missouri, and in late years some of the more handsome forms have been planted for the beauty of their white flowers and red fruit. The fruit varies in size in the different species from smaller than a pea to that of small plums. Those with bright red, medium-sized, sub-acid fruit (*Crataegus mollis* and allied species) are the best for jelly. In cooking they lose the unpleasant flat taste so characteristic of hawthorns and the jelly is much like that of crab-apples.

Each year the common rum cherry (*Prunus serotina*) produces large quantities of red-purple fruit which is seldom used, although in combination with wild apples it makes a delicious dark red jelly, semi-opaque, resembling plum jelly in consistency and flavor.

None of these fruits require any special treatment. After a thorough washing they should be covered with water, the juicier fruits requiring less water, and boiled until soft. The juice is then strained through a jelly bag, and if the resulting pomace has not lost all its flavor more water may be added and the process repeated. (Crabapples can be cooked up in this way four or five times, though the

later boilings sometimes produce a cloudy jelly.) The juice should be measured, and an equal weight of sugar added after the juice has boiled from ten to fifteen minutes. Tests should be frequently made for jelling by trying a small amount on a cold plate or by noticing the way in which it drips off a spoon.—*Missouri Botanical Garden Bulletin.*

RHODODENDRONS THRIVE IN SOIL TREATED WITH ALUMINUM SULPHATE

A METHOD for making the ordinary garden soil suitable for rhododendrons has been discovered by Dr. Frederick V. Coville, botanist of the United States Department of Agriculture, which although still in the experimental stage, will be welcomed by nurserymen and others interested in growing ornamental shrubbery.

Native rhododendrons unlike most plants and crops require an acid soil and will not thrive in the ordinary fertile garden or greenhouse soil, but they grow with great luxuriance in sand mixed with peat, with rotting wood, or with half-rotted leaves. Experiments have made it clear that rhododendrons thrive in this kind of soil because its chemical reaction is acid, and they die in the ordinary fertile soil because its reaction is neutral or alkaline.

Dr. Coville's experimental work which has been done in the greenhouse has shown that aluminum sulphate when applied to an ordinary soil is an effective and inexpensive method of changing the soil reaction from neutral or alkaline to acid. Where soils have been so treated the stimulation of growth of the rhododendrons has been very great, as much as 250 per cent increase in the diameter of the rosettes of seedling rhododendrons having been secured. Crude aluminum sulphate is used in the chemical industries, is not expensive, and in large quantities can be purchased from dealers in chemical supplies at about \$5 per hundred pounds.

Experiments that have been in progress for several years past have shown that soil acidity is required not only for rhododendrons but the azaleas, kalmias, and practically all the plants of the heath family, besides many orchids and numerous other plants of ornamental horticulture that are commonly regarded as difficult of cultivation. There is every reason to expect, said Dr. Coville, that these other plants also can be made to thrive in ordinary soils through the use of aluminum sulphate.

Experimental work in this matter has not been carried on for sufficient length of time to be certain that long continued treatment with aluminum sulphate may not lead to the development of unforeseen difficulties, such as the formation of hydrogen sulphide or other compounds of sulphur injurious to this type of plants. For the present the aluminum sulphate treatment should be regarded as experimental.

Large rhododendrons growing in the deeper soils of outdoor plantings were not tested in these experiments, but for such situations, it is believed, amounts of aluminum sulphate up to half a pound per square yard may be applied advantageously and safely, if the soil is of the ordinary fertile type, the application being repeated if the soil is not made acid by the first application.

In an ideal rhododendron soil aluminum sulphate is unnecessary and useless. Persons desiring to experiment with sickly outdoor rhododendrons are advised to apply the aluminum sulphate to only a portion of the plantings, always leaving another portion untreated for comparison.

Accuse not Nature; she hath done her part;
Do thou but thine. —*Milton.*

Hardy Cypripedium

RICHARD ROTHE

CONSIDERED the showiest of the orchids inhabiting the temperate zones, the species of hardy cypripediums indigenous to our country rank among the most beautiful we know of, but so far we rarely meet them in our gardens. The reason for our frequent failures in attempts to establish and cultivate plantations of our Lady's Slippers or Moccasin flowers, is that we do not, or sometimes cannot, provide the same conditions for their thriving as Nature does. They prefer semi-shady positions and like moisture, but neither stagnant nor excessive moisture. We shall always find them on well-drained ground, their long roots reaching out far, in depth seldom lower than four inches below the surface of a comparatively shallow layer of light leafy or peaty soil, of more or less sandy nature. They inhabit mostly the wooded regions, both in mountainous and lowland sections, and there we may find them from the Middle

Cypripedium acaule

Atlantic States, as far north as Canada. Successful domesticating of our wild growing cypripediums, however, is far easier in New England and northern boundary States than in gardens south of New York.

On account of frequency and wide distribution, cypripedium acaule is perhaps our best known native species. It bears its flowers on straight stems, one foot above its two ground leaves, and we may see it in bloom from May until the end of June, according to latitude. Our photograph was taken during the latter part of June in the small sample rockery I built for the nursery at Northeast Harbor, Maine, about fifteen years ago. Within the exceptionally favorable northern sea-coast climate the color of the flowers varied from white to a deep rosy purple. *Cypripedium parviflorum* and *pubescens* resemble each other very closely, the only means of distinction being the size of their yellow flowers. Those of *pubescens* are noticeably larger than the ones produced by *parviflorum*.

Cypripedium spectabile, recently re-named, and described as *Cypripedium reginæ*, is the stateliest and most beautiful representative of all known hardy Moccasin flowers. Its leafy stalks, nearly two feet high, bear the large rosy purple shaded flowers well above the foliage. This species is wonderfully effective in bog gardens when massed together in clumps of from a dozen to twenty-five plants.

Of the foreign hardy Lady's Slippers, meriting the attention of American garden lovers, I quote, according

to descriptive list given in the new edition of Tarouca and C. Schneider's Standard Work on "Hardy Perennials."

Cypripedium calceolus, native of Central Europe; color reddish brown and yellow. *Cypripedium cordigerum*, hailing from China, Manchuria and the Himalaya; flowers greenish white. *C. macranthum*, a native of Siberia, color of large blossoms deep reddish and pink purple. *C. tibeticum*, northern China, flowers light brown. *C. guttatum*, Russia, northern Asia, rhizomatous, small flowering, white with carmine. *C. ventricosum*, Manchuria and Siberia, color varying from white to bright reddish purple.

Recent new introduction from western China: *C. luteum* in habit of growth resembling *spectabile* but producing light sulphur yellow flowers and *C. margaritaceum* in habit of growth similar to *acaule*.

SOME HARDY GERANIUMS

(Continued from page 119)

above is of the same style, but with a more beautiful foliage and even more magnificent flowers, which share with those of *ibericum* one failing—a short period of blossoming. Still taller, ascending in some kinds to three or four feet, is the old *G. pratense* of our cottage gardens which, in one or two varieties, can still hold its own against the inrush of novelties. Personally, I like the single white and the single blue, especially for the semi-wild garden, and then there is an old variety, now rather rare, which has large double flowers in a very delicate silvery smoke-blue, a plant of surpassing beauty for a cool, half-shady spot.

G. atlanticum also claims notice here. A native, not of the Atlantic Ocean, but of the Atlas Mountains, this species is distinct in more than one particular. It produces a luscious crop of six-inch leafage, like that of some Wood Anemone, above which in May or June stand the erect stems of violet flowers. Then towards the Summer's end the stemless foliage dies away only to re-appear refreshed with the rains of October. Another species of special merit for the rock-garden is *G. Traversii*, which proves hardy though a New Zealander, and one which is at once recognized by its somewhat large, bluntly-lobed leaves, which shimmer with a silvery sheen. There is a white form of *G. Traversii*, also some with flowers of a washy blush, none of which can compare with the variety sometimes listed as *var. elegans* in which the blooms, which open flat, are nearly two inches across and of a most refined and exquisite shell-pink.

From the last-mentioned one might easily be persuaded to enter those entrancing pastures in which dwell the many silvery-leaved little treasures of the rock-garden. But, even if space did not forbid, the pitfalls of classification might bring one to confusion amid the shoals of *Erodium*. So I must content myself with a mention of the new *G. "Russel Prichard,"* which suggests a blend of *sanguineum* and *traversii* in its blood-red flowers and silvery foliage, and wind up with a regret that the many good American species of this genus are still so uncommon in English gardens. *G. Fremonti* and *cæspitosum*, *Richardsonii* and *sessiliflorum* we have, but even these are anything but well known.

The heart that is soonest awake to the flowers is always the first to be touch'd by the thorns.—*Moore*.

FLOWERING EVERGREEN SHRUBS

THERE is no need to point out to a practical gardener the importance of evergreens in the garden scheme. There is, indeed, a regrettable tendency in some quarters to use them in unsuitable places. There was a time—not so very long ago—when it was considered proper to clothe the table legs. This attitude we very properly deride, yet, even today, one often sees the butts of fine forest trees obscured by meaningless evergreen planting. Such planting effectively destroys the balance and grace which, with the appearance of strength and solidity, constitute the charm of a well grown tree.

The value of evergreen shrubs admitted, there seems no reason why a much greater proportion of those used should not be flowering shrubs than is at present the case. There are very few positions where the fact that a shrub at some period of the year bears attractive flowers (or handsome fruits) is a disadvantage.

Yew and Holly, each in its particular way, are, of course, admirable hedge plants. They also have decorative values as trees. Laurel has none of these advantages. It is an unsatisfactory permanent hedge and, as usually seen, cumber ground which might be occupied by more beautiful as well as more interesting shrubs.

If a substitute be sought with something of the same leaf character, there is a multitude of hybrid Rhododendrons to choose from, to say nothing of the ever-swelling legion of large-leaved species. The so-called American Wood-Laurel, *Kalmia latifolia*, is also charming when in flower and valuable as flowering when the bulk of Rhododendrons are over, though the Rhododendron season, with new introductions, grows steadily longer. On soils with an appreciable lime content these Rhododendrons will not grow, but large-leaved flowering evergreens are still to be found. We have the so-called Strawberry Trees, for example, *Arbutus Unedo* and its varieties, *A. Andrachne* and the hybrid between the two species, *A. hybrida*, none of which objects to lime. *Cistus laurifolius* is also worthy of mention, since it forms a good solid background when out of flower though, of course, its leaves resemble the Laurel only in shape—not in size. It is a most attractive shrub when in flower.

The same may be said of the large-leaved Escallonias which, on well drained soils, are much more handy than many people suppose. The two hardiest large-leaved species are *E. macrantha* and *rubra*. Of these two *E. rubra* is usually considered the hardier, but, in the writer's opinion, this is exceedingly doubtful. *E. punctata* is handsomer than *E. rubra*, but scarcely so hardy, yet it is an invaluable species for the southern edge of woodland, or for sheltered sites generally, in any of the coldest districts.

Then we have the broad-leaved Barberries which to most of us are still "Mahonia." There is the old favorite Oregon Grape itself, *Mahonia aquifolium*, invaluable for underplanting. Then there is *Berberis japonica* and its several varieties (including the one generally listed as *B. Bealei*), *B. nepalensis* and *B. nervosa*.

There are several useful evergreen Cotoneasters which, if of small value as flowering shrubs, are admirable when in fruit. These include *C. Francheti*, *pannosa*, *buxifolia*, *salicifolia* (and varieties), and *turbinata*. Of prostrate sorts *C. microphylla* and *Dammeri* are reliable and beautiful fruiting shrubs. All the *Pyracanthas* are also delightful fruiting evergreens.

Of evergreen Ceanothuses the only one likely to succeed in the open inland without considerable protection is *Ceanothus thyrsiflorus*, the so-called California Lilac, which in time reaches the stature of a small tree. The flower trusses, which are of fair size, are pale blue. The variety *griseus* is almost as hardy. It has much larger foliage, is a quicker grower and the blossoms are pale

lilac. Moderately hardy, too, is *C. Lobbianus*, now considered to be a natural hybrid between *C. thyrsiflorus* and *C. dentatus*. This is a bright blue-flowered kind, often seen in gardens as *C. dentatus*. This muddled nomenclature leads to much confusion as to the hardiness of various families of plants which are not, in general, entirely hardy.

The Mexican Orange, *Choisya ternata*, is unquestionably far hardier than most people consider it. Given shelter from wind-frost it will withstand very low temperatures unharmed. Its beauty none will deny. The *Raphiolepis* has the same highly glazed foliage as the *Choisya*, but in general appearance these shrubs remind one more of the Escallonias than anything else. The two hardiest species are *R. japonica* and *Delacouri*, the former with white and the latter with pink flowers.

That beautiful and fragrant relative of the Mock Orange, *Carpentaria californica*, requires a wall in most districts, though it makes a beautiful shrub in the open on our western seaboard. It flowers about mid-Summer, a time when shrub-flowers are welcome. The same way, with equal truth, be said of *Garrya elliptica*, though it certainly resembles the *Carpentaria* not at all. The handsome catkins in this case are at their best in the depth of Winter.

Rosemary and Lavender once used to be in every garden. Alas! they are so no longer, yet both are admirable evergreen (or rather evergrey!) shrubs, and the latter is really beautiful, as well as fragrant, when in flower. There is now much variety obtainable in Lavenders, the true Lavender, *Lavandula vera* being obtainable in pale and dark forms, as well as in forms of varying degrees of compactness.

There are, of course, many beautiful American plants still unmentioned, notably those of the Andromeda clan—such as *Pieris japonica* and *P. floribunda* and *Leucothoe Catesbæi*, besides the Heaths. Tall varieties of the latter which are very effective include *Erica australis* and *E. arborea* (and variety *alpina*), *lusitanica*, *mediterranea*, *Veitchii* and *stricta*.—*The Garden*.

STIMULATING PLANT GROWTH WITH CARBON DIOXIDE

(Continued from page 121)

off at 6 to the sewer. Here the gas is partially purified.

To still further clean it, the gas passes through pipe 3 to the second and last scrubber. Here a solution of soda (Na_2CO_3) is used in place of the water in scrubber number one. This liquid is not lost, it collects at C, passes through pipe 7 into tank E. From this point it is pumped at F to the top of the scrubber at 2, from whence it is sprayed over the coke again.

The gas, coming from the top of the second scrubber, is now clean and pure, and is carried to the ventilators or pump D, from which it is distributed through pipes to the greenhouse. This pump also serves the purpose of bringing fresh air into the boiler, its action being somewhat similar to that of a forced draft.

The pipes which distribute the carbon dioxide gas in the greenhouse, pass about one foot above the plants, and are provided with tiny holes about a foot apart. The process of gassing is considered complete when 2 or 3 per cent of carbon dioxide has been provided which, of course, gradually dissipates. Larger quantities of gas are injurious, therefore ventilation must be carefully watched to avoid the effects of an overdose. The results obtained with this patent process justify the remark that this method of growing plants quickly and comparatively inexpensively will ultimately become universal where the most progressive growing methods are practised.

California Waysides

OLIVIA BROOKS

I AM going to tell you something about some of the native shrubs I have seen while motoring in my "Ford" through the country surrounding San Diego, for, many and interesting are the different varieties growing in the mountains, valleys, and along the seashore. One always waits with keen anticipation for the coming of Spring in California, knowing that after the rains of January and February, the wild flowers begin to bloom, as also do many of the shrubs.

The enthusiastic botanist is thrilled with delight at finding, not only old friends, but making new ones amongst the great display of beauty and color that meets one on all sides from San Diego to the northern part of the State.

Around San Diego there are three interesting sumachs, all evergreen—the laurel leaved (*Rhus laurina*), "lemon-and-sugar-tree" (*Rhus ovata*), and the "mahogany bush" (*Rhus integrifolia*). These varieties belong to the same family as our eastern sumach, with pinnate leaves and long cardinal-red fruit clusters, which is so handsome growing along the roadside in the Fall.

The laurel leaf sumach (*Rhus laurina*) is the most common of these three shrubs, growing in great abundance on the lowlands, the foot-hills and well into the mountain regions. It is from six to fifteen feet high, of a wide spreading, bushy growth, with narrow and pointed, dull green foliage.

The new leaves, being red, stand out conspicuously, giving the whole shrub a bronze color. The flowers are white, in long clusters, said to be quite pretty, unfortunately I have not seen this shrub in bloom, as it blossoms in Summer.

The lemon-and-sugar-tree (*Rhus ovata*), a compact shrub six to eight inches high, is found only on the foothills well into the "back country." The handsome, shiny, ovate leaves are leathery in texture with an entire margin, and the rose pink flower clusters are so numerous that one is at once attracted to this shrub by its unusual amount of color. The berries are coated with a sweet substance which the Indians value as a substitute for sugar.

The "mahogany bush" (*Rhus integrifolia*) is a tough rigid growing shrub, which makes splendid compact hedges in gardens along the Pacific, where it takes most kindly to cultivation. Its leaves are dull green, thick, and rather serrated; the lovely, tiny pink blossoms seem to redeem this stalwart shrub, making it more delicate and pleasing to the eye. The little drupes are covered with an acid, oily substance, and are used by the Indians and Mexicans in making a lemonade-like drink.

One of the best known shrubs in California is the manzanita (*Arctostaphylos manzanita*). I have seen it growing all the way from a well developed small shrub to a typical tree. The flowers which bloom about Christmas time, are much like those of the blue-berry, belonging to the same family.

The manzanita has a great deal of character among the wild shrubs, for its smooth, satiny, red bark is most distinctive in contrast to the pale green leaves and tiny pink blossoms that cover the branches.

The name "manzanita" is Spanish for "little apple," and well describes the fruit of this bush.

"Indian Tobacco" (*Nicotiana glauca*) is the most widely distributed shrub along the roadside, in fact, I don't believe I have seen it growing anywhere else. It has spread rapidly, as residents can remember when there

were very few of these plants, which originally came from Buenos Aires. The shrub has a loose spreading habit, fifteen feet or more in height, with lovely, waxy flowers, long and tubular in shape, greenish yellow in color, hanging in graceful clusters.

The wild lilac of California (*Ceanothus*), which has so many varieties, is always an interesting sight to see, for, at its height of bloom it forms an amazing sweep of color from the foot to the top of a hill, filling the air with a delicious fragrance. It is a graceful, evergreen shrub, with small leaves, amongst which appear diminutive clusters of tiny, airy blossoms.

In December the most wonderful shrub seen along the sea-coast and in the foothills, is the California "Holly" or Christmas Berry (*Heteromeles arbutifolia*). This handsome bush was fast being exterminated by ruthless "wayside marauders," but now stands protected by law.

I have never seen anywhere on any plant, such large and magnificent clusters of red berries, making the whole hillside fairly glow with color!—a sight to be stored away for future thought. The Christmas berry has not the prickly leaves of our eastern holly, but oblong, serrated, leathery foliage.

The Chamise (*Adenostoma fasciculatum*) forms a great part of the Chaparral on the mountain slopes. Its dark green, almost black needle-like foliage, very feathery in appearance, makes a most effective background for the other wild plants that grow about.

One could go on indefinitely describing these wild shrubs, all so distinctive in character, and beauty of form, but being familiar with even a few adds interest and friendliness to any landscape.

NEW ENGLAND ASTER

THE New England Aster has become such a favorite that one hesitates to say anything about it. So much has been said in praise of this really beautiful species that its admiration has become something of a fad, and one suspects that a few of those who tout it so highly are just a wee bit insincere, writes Frank A. Waugh in *Florists' Exchange*.

Another curious thing about this species is that, although it is one of the most striking wild plants of our region, it has secured its extreme popularity in the planting of old-fashioned hardy perennial gardens which are in fact more or less formal. No complaint need be made about the use of the New England Aster in formal or semi-formal gardens, but we should not lose sight of the fact that it is one of the very best species for extreme naturalistic effects also. As it occurs in wild masses along streams or the borders of ponds it is magnificent.

A caution needs to be given with respect to the selection of colors. The species varies quite widely in the color of its flowers, including pink, rose, blue and purple and some of these shades fail to harmonize when placed together. In general it will be found that varieties of clear rose or amethyst blue are the most agreeable to the eye.

Still another point needs to be noted, viz., the beauty of this Aster in the Winter garden. Of course it is a fact that the beauty of the Winter garden is too much neglected by all of us. Nevertheless it is there and not always overlooked. The good landscape architect, at any rate, endeavors to make his gardens attractive at all seasons and should not forget the charm of the New England Aster as it appears under a mantle of fluffy snow.

RHODODENDRONS IN A DRY SUMMER

WE know of no hardy evergreen shrub that feels the effect of a dry Summer more than the Rhododendron. An experienced eye will be able to tell by a glance at the foliage whether the plants require water or not, because no hardy shrub shows more plainly than Rhododendrons that the roots are dry. If this is the case, they have a distressed appearance, the leaves hang down, and, in bad cases, the points of the young shoots droop also, so that altogether the plants have an unhappy look. Plants in this condition will not flower satisfactorily next year, and in bad cases not at all, for the reason that they cannot form flower-buds, owing to their distressed condition.

Those who have choice varieties of Rhododendrons should examine the soil round the roots to see if it is dry, and if such is the case give them a thorough soaking of water at once, repeating the application once a week during the Autumn, for these plants suffer as much in the Autumn, if the weather is dry, as they do in the height of Summer. The swelling of the flower-buds which is going on through the Autumn appears to tax the resources of the plants a good deal. The plants that will be likely to require attention first are those which occupy positions somewhat elevated, such as on sloping banks or raised beds. They are also likely to suffer from the want of water when the plants stand as isolated specimens on grass, and more particularly when the soil has to be made for them, as in such cases the roots have only a limited root-run in a suitable soil. The best plan to follow in any case where water is given to the roots of trees or shrubs is to apply it first and then mulch the surface directly afterwards. The mulching should be laid on 3 inches thick, and renewed as often as it becomes wasted. Where liquid manure is available, a liberal supply of it would also do good, but the roots of the plants should be first soaked with ordinary water, so that they may have the full benefit of the stimulant.—*Gardening Illustrated*.

AN APPEAL FOR THE WILD FLOWERS

STRANGELY enough, what is called civilization has, in many parts of the United States, destroyed many of the rugged beauties of the woods and hillsides, without putting anything in their place. Perhaps in New England, more than elsewhere, many of the beautiful things have been preserved. The farms have not encroached so relentlessly upon the woods as in the sections of the middle west and south, where land is more valuable. The mountains, too, remain a forbidding barrier to the thing called progress, and stand as sentinels over the treasures which they have guarded for centuries.

But modern invention has made it possible for the predatory tourist to extend his invasions farther and ever farther from the beaten path. Where he goes he is too often inclined to destroy, to take what he desires and leave nothing in its place. His camp site in the woods is a place of desolation as he strikes his tent and moves on. To the tourist family the wild flowers and the blossoming trees seem to offer the opportunity for the practice of vandalism. Nothing is safe from the hands of the greedy visitors.

In a bulletin recently issued by the University of the State of New York, an appeal is made to save and protect the wild flowers. It is shown that they are gradually disappearing even from those sections where once they were common. It is not what one person or one company of tourists gathers. There are still enough wild flowers for the thousands who will gather them thoughtfully and considerately. The menace to the wild life of the roadside

and woods is the greed of the city dweller who assumes that all he can find is his for the taking.

It should be remembered that the wild plant is like the cultivated shrub or flower in the garden. It is as easily destroyed, and it responds as quickly to the considerate treatment which it deserves. Those who gather flowers along the way are admonished to pick them carefully, just as they would select a bunch of blossoms from a garden or a conservatory. The unmatured blossoms left upon the stalk may flower and seed, thus renewing and increasing the beauty of the place, whereas a plant torn up from the ground and thrown aside is destroyed.—*C. S. Mouton*.

AQUATIC AND WATERSIDE PLANTS

AQUATIC and moisture-loving plants are extremely fascinating. May and June is undoubtedly the best time for planting or transplanting Nymphæas. I have seen it stated that it is necessary to have three or four feet of water for the Marliac varieties of Walter Lilies, but this is misleading; granted they will do in that depth of water, but I know from experience they succeed splendidly in water only one and a half feet to two feet deep. Young plants obtained this time of the year (May or June) may be very easily established. If for tanks with cement or concrete bottoms, planting in shallow baskets will be found the best method of establishing them in the water, placing in a few pieces of sandstone around them when in position to form a basin and filling in round the basket with rich turfy loam. This will keep the plants in good condition for many years after the baskets have disappeared. If the plants are required for ponds with ordinary muddy base, an easy and successful method of planting is to secure some thick turves of loam and tie one round the roots of each plant. Wire will be found better than string for keeping the loam in position until the plants establish themselves. Sufficient loam should be used to ensure keeping the Water Lilies upright when sinking them in their respective positions.

For waterside planting the following are all very beautiful aquatics and if submerged at various times during the year they will come to no harm. The Siberian Irises are charming both in flower and foliage for the leaves are quite graceful, giving a glorious effect at the waterside.

Iris Kämpferii, the Japanese Flag Iris, is splendidly effective in pockets by the water edge. Astilbes may also be used for the margins of lakes and ponds with grand effect.

Funkias in variety are noble subjects, with their massive foliage; Hemerocallis (Day Lilies) may also be used for the same purpose, with beautiful effect; both their orange and yellow spikes of blooms and graceful foliage are attractive in association with water.—*The Gardeners' Chronicle* (British).

TO OUR READERS

You have friends who would welcome the GARDENERS' CHRONICLE as a regular monthly visitor to their homes, just as you do, if they were familiar with it. We shall be glad to send a copy free to any address you may send us to make known how valuable and instructive a guide it is to all interested in gardening. We are constantly endeavoring to make the GARDENERS' CHRONICLE better and better—not with the assistance of Coué—but through our own individual efforts and you can help, if an idea comes to you that would make the GARDENERS' CHRONICLE even more interesting, if you will send it to us. It will be appreciated. EDITOR.

Planting Trees As Memorials

IN California we have the greatest trees of the whole world—the sequoias, write Pearl LaForce Mayer in *California Garden*. The sequoias are not only the oldest living things on earth but they are the tallest trees on earth and yet these are the trees that men have been cutting for boards and shakes and shingles! The known age of many of these sequoias which have been cut is from 1,100 to 3,250 years and when they are gone they can never be replaced!

John Muir, the great naturalist and tree lover says: "The forests of America must have been a delight to God for they were the greatest He ever planted!" The whole continent was at one time the most beautiful park of the whole globe as we can tell from fossil remains of trees and plants.

All other civilized nations are compelled to take care of their forests and continually replant them, but the Americans have been most prodigal in their waste of this marvelous natural resource. It is but in the past few years that we have begun to wake up to the fact that we must conserve these trees or very soon we will have none.

Theodore Roosevelt said: "A people without children would face a hopeless future; a country without trees is almost as hopeless; forests which are so used that they cannot renew themselves will soon vanish and with them all their benefits. When you help to preserve our forests or to plant new ones you are acting the part of a good citizen."

And Henry Van Dyke tells us:

He that planteth a tree is a servant of God;
He provideth a kindness for many generations,
And faces that he hath not seen shall bless him."

Again John Muir tells us that "Any fool can destroy trees. Through all the wonderful eventful centuries since Christ's time and long before that God had cared for these trees (in America) but He cannot save them from fools—only Uncle Sam can do that."

Every child should be taught both the material value and the æsthetic value of trees and to love and care for them in every way, and never to deface a tree no matter how large or small it is and no matter where it stands.

"He who plants a tree his name is blessed! But for him who ruthlessly destroys a tree—what shall his name be called in any tongue?"—so says the great Chinese philosopher.

From the earliest days of creation men have recognized the psychic personalities among the trees and in the annals of every great religion trees have stood forth prominently. In all great art and literature the subject of trees has been highly accented and the great men of all ages have felt a peculiar kinship with the trees.

James Russell Lowell speaks of this in the following verse:

"I care not how men trace their ancestry,
To ape or Adam; let them please their whim;
But I in June am midway to believe
A tree among my fair progenitors.
Such sympathy is mine with all the race,
Such mutual recognition vaguely sweet
There is between us,—surely there are times
When they consent to own men of their kin,
And condescend to me and call me cousin."

To all those who are well acquainted with them, trees are living, loving personalities and possess many habits and attributes which most people think are exclusively human.

Within the last few years the custom of planting trees for memorials has gained greatly in favor and in fact

what could be a more beautiful memorial than a tree? How much more wonderful to have a lovely green tree living in honor of one than to have the most expensive of stone monuments?

Felix Oswald says: "I can think of no more pleasant way of being remembered than by the planting of a tree. Birds will nest in it and fly thence with messages of good cheer. It will be growing while we are sleeping, and will survive us to make others happier."

"If thou art worn and hard beset
With sorrows that thou wouldst forget,
Go to the woods and hills! No tears
Dim the sweet look that Nature wears."

From time immemorial certain trees have always been used to represent certain ideas of spiritual significance. The palm has always been used to represent victory. It has dignity, poise and strength softened by attractive and kingly grace and it embodies exultation and joy.

The pine to us is an emblem of immortality. To the Japanese it signifies good luck and is supposed to bring long life and happiness. A pine tree is always seen gracefully leaning above a Japanese garden gate or at some picturesque spot along the garden wall.

The orange tree symbolizes prosperity, the olive achievement and so on down the long list of these benefactors of mankind.

"Hail to the trees!
Patient and generous, mothers of mankind;
Arching the hills, the minstrels of the wind;
Spring's glorious flowers and Summer's balmy tents.
A sharer in man's free and happier sense.
The trees bless all, and then, brown-mantled, stand.
The sturdy prophets of a golden land."

FOR AMATEUR DAHLIA GROWERS

DIG deep and a good square hole, throw out the subsoil and fill in with good surface soil.

Do not use too much coarse manure in the hole, better reserve same for a mulch.

Fine ground bone thoroughly mixed with the soil some time previous to planting, if possible, is a good substitute for manure. A much more dwarf sturdy growth will be obtained with the bone and the probability of more blooms, as bone does not create as much leaf growth as manure.

Set a good stout stake either before or at the time of planting; setting after the plant has started to grow often disturbs or breaks the roots.

Take the top out of the plant when a foot high; this keeps the growth near the base of the plant, no necessity for two or three feet of bare stalk.

In cutting blooms do not be afraid, cut down good lengthy sprays. Never mind if you do cut some few buds with the spray. The others coming after will be larger and better.

With some varieties if the side buds are picked off of the spray (disbudded) it will increase the size and quality of the bloom.

If you have a mulch around your plant of sufficient size you can water at any time of the day without baking the soil and the mulch will help retain the moisture.

Don't work the soil when it is wet. Often failure comes from this cause.—*Bulletin of American Dahlia Society*.

Nothing has such power to broaden the mind as the ability to investigate systematically and truly all that comes under thy observation in life.—*Marcus Aurelius*.

ON GROWING NARCISSI IN AMERICA

SINCE the Federal Horticultural Board of the United States Department of Agriculture has decreed that after 1925 the free importation of narcissus bulbs shall be forbidden, William H. De Graaff, scion of the House of De Graaff of Holland, which for three generations has been specializing in daffodils and tulips, has been traveling in this country to find soil and climatic conditions which will make the successful commercial production of narcissi in this country possible.

He has visited the Pacific Coast, particularly studying the Willamette Valley section, and recently has been going over the conditions on Long Island, New Jersey and

William DeGraaff and John Scheepers

South Carolina, and feels firmly convinced that it will be impossible to successfully raise narcissi for commercial purposes.

Before sailing for Holland, he expressed his regrets that some of the Holland jobbers of bulbs are inducing farmers and growers in various parts of this country to buy large quantities of planting stock of various daffodils, which is not only doomed to failure but is bound to deplete the stocks available in Holland and is certain to cause an advance in prices of bulbs for delivery this Fall and for next year.

The House of De Graaff was among the first to start the scientific production of narcissus bulbs on a large scale. Many new and meritorious varieties now listed in catalogues were produced by this firm and many great novelties have won highest awards at the recent narcissus shows in Holland and England. The accompanying illustration shows Mr. De Graaff with John Scheepers of New York so-journing at Atlantic City.

MASSACHUSETTS AGRICULTURAL COLLEGE

The Department of Floriculture at the Massachusetts Agricultural College, Amherst, Mass., will conduct a special one week course in commercial floriculture for the florists of that state, beginning June 25.

The program will be announced in this paper at a later date. It is hoped that those interested will keep this date in mind.

The Lord and Burnham Co. has donated to the college a model greenhouse, 11 feet by 8 feet 4 inches, of their No. 1 and No. 2 greenhouse construction, which will prove invaluable in the teaching of greenhouse construction. A set of blue prints has also been provided for each student. The department wishes to express its appreciation to the Lord and Burnham Co. for their kindness and co-operation in making its work more efficient and of greater benefit to the students and florists.—R. T. M.

SEEDING LAWNS IN LATE SUMMER

SPRING is not the best time for seeding lawns; late Summer is vastly better. Seeding done at that time, while the days are growing cooler and plants get the benefits of heavy night dews, insures a good lawn the following Spring, writes a contributor to the *Florists' Review*. There can be no certainty of lawns seeded in Spring being a complete success, unless an ample water supply is at command. Plants seeded in Fall have deep roots and withstand the Summer droughts far better than the former. Far too much work is left each year until the overcrowded Spring season. This applies to the planting of trees, shrubs and hardy herbaceous perennials. Some day, it is to be hoped, more people will appreciate the great advantages to be gained by Fall planting.

But to refer back to lawns, there are always many calls for work on lawns at this season. Entirely new lawns should be liberally manured, care being taken to bury the manure well. You should rake the lawn most thoroughly, in order to get rid of as many roots, stones and weeds as possible. It should be made firm by tramping or rolling, according to the size and nature of the ground to be sown down, in advance of any seeding. Iron rakes should then be used to loosen the surface before seed is sown. There are some good mixtures of lawn seed offered. As a general rule, some of the grasses included are ill adapted for the average lawn and will usually disappear the first Summer. Special grasses are needed in the warmer states, but for the more northerly ones the writer has found Kentucky blue grass the best stand-by. Two parts of this grass to one part of redtop makes an excellent mixture, and, if white clover is liked, add that at the rate of one pound to twenty-five pounds of other grasses.

The clover is especially helpful in light soils. It will retain its greenness during droughts and adds much fertility to the soil. It is best to sow lawn seed fairly thickly, and in seeding be sure to go over the ground both lengthwise and crosswise, in order that there may be no bare spots. A thorough raking and hard rolling must follow seeding.

THE CHRIST-AWAKENING

MARIAN J. COBB

How sweet the story of that long ago,
When the disciples sailed at close of day,
And as the ship launched forth, the Master lay
Asleep upon a pillow, resting so.

But as he slept, the angry waves did break,
For o'er the sea a sudden wind-storm swept;
While the disciples rushed to where he slept,
Crying, "Awake, we perish! Master, wake!"

Then he arose; and with his "Peace, be still,"
Rebuked the winds, and bade them do no harm.
The tempest ceased; and lo, there was a calm;
The waters fell, obedient to his will.

Sometimes, the Christ-idea seems asleep
Within my fragile bark, the ship of life.
Ah, then it is that winds and storms are nigh,
And angry waves engulf me, mountain deep.

But when, at length, through faith and love and prayer,
The Christ awakens in my consciousness,
The healing Christ, that wakens but to bless,—
The tempests cease; and lo, a calm is there.

To that sweet story of the long ago,
My thought again, and yet again, hath turned;
For in its deeper meaning I have learned
The sweetest lesson that the heart can know.

Christian Science Sentinel.

Foreign Exchange Department

THE ROCKY MOUNTAIN COLUMBINE.—It would be difficult to name a Columbine which is quite so attractive as *Aquilegia cœrulea*. It also possesses the merit of being distinct, the perfectly upright poise of the flower at the head of the stem being a characteristic almost unique among its kind. This very lovely species is of somewhat slight growth, yet quite rigid and erect. The comparatively scanty, glaucous foliage, small-leaved and delicate, is mainly gathered about the base of the flowering stem, which latter ascends to the height of about 1 foot. The long-spurred blossoms are very large, creamy white in the centre, the remainder being a good firm blue with perhaps the slightest hint of cool lavender to complete a most delightful tone. These flowers open early (before most others), and this is a matter of no small moment, since it ensures a crop of true seed, which is a boon to many who have to treat *A. cœrulea* as a biennial. This plant, however, is by no means always difficult. It is often quite permanent in gardens, where it can be afforded a gritty, or even stony, soil with some leaf-mould. But while it must not be too sodden in Winter, it undoubtedly enjoys a cool root-run, such as a rock garden ledge sloping to the north-west might afford. Seed germinates quite freely and the young plants give no trouble.—*The Garden*.

THE AFTER-CARE OF AZALEAS.—No hard-wooded plant is more beautiful in its season of flowering than the Azalea, and in the hands of an amateur gardener, unfortunately, no plant receives less consideration immediately its blooming season is over. In numerous small houses Azaleas are hurriedly withdrawn when the flowers have faded, to make way for something else coming into beauty. It is the harsh treatment meted out to these showy flowering shrubs which makes for failure the following season. Too seldom does the amateur recognize the importance of continuing the plants in the same genial atmosphere, with attention to watering and syringing to induce new growth, before any attempt should be made to place the plants in cooler quarters. I am not drawing an imaginary picture when I say that a cold frame in Spring, where the temperature at night approaches freezing point often, and where the roots are allowed to become dry, does not conduce to an output of new growth, yet one may see this every year. Surely, the beauty of Azaleas is such as to warrant special attention being given them as soon as their blooming season is over, and to pay regard to watering, bearing in mind the close, retentive nature of peat in which they are grown. With all hard-wooded plants, when watering is needed it ought to be done thoroughly to ensure the roots getting full benefit.—*Gardening Illustrated*.

ENOTHERA SPECIOSA.—This North American plant is lovely, carpeting a bed of La Tosca Rose. The large, satiny white flowers, which change to a rosy shade with age, are produced in great numbers upon the 18-inch stems, and are lovely by day, as well as at night, when their charming fragrance is more in evidence. It is a choice and graceful plant, with wiry stems, and is most desirable and lasting as a cut flower. Although of perennial character, it is not strictly hardy everywhere, for which reason a few cuttings should be taken about the end of September each year and placed in a closed frame, where they strike freely.—*Gardening Illustrated*.

DIGITALIS AMBIGUA.—There is much to be said for the yellow Foxglove as a plant for the sunny or shady border, or for naturalizing in the woodland garden or shrubbery. Though much lower in stature than the common native species, *D. ambigua* is very rigid and erect, not given to being blown over, nor does it look shabby when the bells begin to fall. The prettily tapered spikes (about 18 inches) rise from a tufted rosette of long, pointed leaves of a rich green, and smaller leaflets of the same narrow form grow upon the lower parts of the flowering stem. This species has, moreover, a perennial nature to recommend it, and it will, as has been suggested, produce self-sown seedlings in any suitable situation. The flowers are a good size and much superior in color to those of *D. lutea* or *leucophylla*.—*The Garden*.

POTENTILLA NEPALENSIS WILLMOTTIÆ.—If it were only on account of its long blooming season this *Potentilla* would rank high among rock plants, for it is the first to come into flower in early Spring, and carries on until nearly Christmas. It has, however, other claims to attention, among which is the lovely cherry red of its wide-open flowers with their eyes of jet set off by anthers which sparkle with gold dust. *P. Willmottii* is, moreover, very easy to please, asking no more than a sunny spot in any free soil, and there it will prove quite hardy and permanent. It is as neat and orderly in shape as it is beautiful, and seldom exceeds 6 inches in height.—*The Garden*.

GILLENIA TRIFOLIATA.—For a cool soil, or bog, with or without shade, *Gillenia trifoliata* is a plant whose grace of form will win it a place among the choicest *Spiræas*, to which it bears some affinity. This is a herbaceous perennial, quite hardy, growing up to about 2 feet, and making a bold mass of its three-lobed leaves and many-branched stems which terminate in the flower sprays. These latter are not showy, nor are they produced in any great abundance, but the little white stars are very refined and delicately beautiful.—*The Garden*.

LINNÆA BOREALIS.—The Twin Flower of northern forests, *Linnaea borealis*, is the delight of all who can please its capricious nature and the despair of all to whom it will offer no response. Yet it is not as difficult a plant as many alpine. What it chiefly needs is a cool root-hold in a sweet old vegetable mould and, if possible, a half-buried and mossy decayed stump over which it can send its prostrate trailing growths which root as they proceed. A half-shaded or quite sunless spot appears to suit this plant best, although when established it will often do well in full sun. Frequent sprayings during the first Summer, with shelter from parching winds, are undoubtedly helpful. The two flowers, which are borne on short, erect stems at intervals along the creeping branches, are a delicate rose pink and indescribably dainty. *L. americana* (*canadensis*) has rather larger blossoms of a slightly deeper color. This form which, by the way, is more amenable to cultivation, flourishes all through the more westerly woods of the Canadian Rockies and extends right down to the sea in British Columbia, making any moist and mossy place its home.—*The Garden*.

CUTTING AND PACKING FLOWERS.—To cut and pack flowers at once is a mistake, especially during hot days, when much of their moisture will have been evaporated, and they are liable to lose the rest by breeding or absorption. If the flowers are to be sent away early in the morning they are best cut overnight and packed in pans or jars of water, and they should be cut in the morning and similarly treated if they are to be despatched in the evening. They will thus be perfectly fresh and their stems charged with moisture. Roses especially should not be packed in a full-blown state; to be really serviceable when they reach their destination, they ought not to be more than half-blown when cut. Most other flowers should be fully expanded, and should be cut as soon as that stage is reached. It is only a disappointment to send anyone a quantity of single pelargoniums, as, unless these are gummed, they are certain to fall to pieces, and there are a few other single flowers that are not much better in that respect. Water lilies, which are so much prized, should be cut and packed when the buds are just bursting, and those receiving them must open the petals with the hand. The iris family should also be packed in a bud state; primroses, snowdrops, pansies, and other small flowers are best bunched, and these will thus be found to preserve one another. Many err in being too cautious—do rot, in fact, pack the flowers close enough. The lid ought always to fit down tightly, as the flowers are certain to shrink somewhat, and, being laid flatly and closely, are not so easily crushed as some may imagine. Wooden boxes are the best to use. There is no better packing material than clean fresh moss, and no worse than cotton wool, which robs the flowers of their moisture, sticks to them, and spoils their appearance.—*Gardening Illustrated*.

PROPAGATING RHODODENDRONS.—The best method of propagating rhododendrons is by layers. This is far better than grafting, but, unfortunately, only a few nurserymen adopt layering to increase their stock. Layered plants make the handsomest bushes, and, of course, one is not troubled with suckers of the *R. ponticum* or other kinds employed as stocks. The layers may be put down in Spring, and again in early Autumn. Peat with a quantity of sand added is the best soil in which to insert the layers. The lower branches must be utilized for the purpose. If they cannot readily be brought down to the ground, you may cut a notch halfway through the branch, so that it will bend but not break away totally from the parent plant. Last season's growths make the best layers. Strip off a few of the lower leaves, then take the shoot in the left hand and make a cut about 1½ inches in length with a sharp knife up the centre of the shoot. This is technically called tongueing the shoot. A flat layering-trowel, with a straight edge, should be at hand. Insert this in the soil so as to make a cut about 5 inches or 6 inches deep. Then bend the prepared shoot very gently, and fix into the soil with some wooden or wire pegs in such a manner that the tongue formed by the cut points downward. See that it rests upon the soil at the bottom of the opening made by the trowel, then press the soil firmly around the layer with the handle of the latter, and the operation is complete. If dry weather supervenes, a watering now and then will be beneficial. The layers make the best plants if allowed to remain on the stool two years, although they will root more or less freely in twelve months. The flower-buds should be removed from the layers before inserting in the soil.—*Gardening*.

Brief Horticultural Jottings

One of the most beautiful of Spring-flowering shrubs, of comparatively large growth, is the male form of the Goat Willow, *Salix Caprea*. Before the frost is hardly gone, the large ovate spikes of yellow anthers make a brilliant show. In addition to its appearance, it has a fragrance which is agreeable to most persons. The female form is far less handsome. What is known as the Kilmarnock Willow belongs to this species—this being the female form of the same species, which has assumed a weeping habit. This is almost destitute of fragrance.

Considering the great beauty of the male, it is rather surprising that it is not more generally employed in ornamental gardening. The weeping variety of the female form is grafted on the male, and very often the grafted portion dies away, leaving only the stock living, and it is chiefly from these stocks that the male plants, occasionally seen, have been distributed, for there has been very little demand for the male plants directly from American nurseries.—A. McL., in *Mechanics' Monthly*.

According to the *Kew Bulletin*, the famous tree known as the Big Tree of Tule at Santa Maria de Tule, eighteen miles from Oaxaca, Mexico, is the oldest in the world. This tree is closely related to the swamp or deciduous Cypress (*Taxodium distichum*), and is known to botanists as *T. mucronatum*. Its height is about 150 ft., the diameter of its trunk is 50 ft., and its age is supposed to be about 5000 years. In 1908 C. J. Chamberlain, of the University of Chicago, saw the tree, and it was then in perfect health, not a dead twig being in sight. "Before the Pyramids of Egypt were built it was a sturdy tree, and before Moses led the children of Israel into the wilderness it must have reached the usual size of the species; when Rome was founded it must have been known as a big tree."

The International Horticultural Congress assembled at Ghent has decided to submit complaints to the League of Nations because of the restrictions decreed by the United States on the importations of plants under the pretext of disease. It was also decided to refuse to supply the United States with specimens of any new varieties.

The English delegates did not vote. It is stated that Americans do not refuse to admit on the grounds of disease new plants from Europe which they themselves desire to cultivate. As the American action affects all countries, an international effort will be made to arouse American public opinion on the question.

At a recent meeting of the American Rose Society J. Horace McFarland reported he fears that as a result of the death of Congressman Mann, the proposed rose show garden in Washington, D. C., of which he was one of the active supporters, has received a serious set-back and without his support may fail to become a reality. Elaborate plans for the garden have already been drawn up by Olmstead Brothers.

While visiting the tomb of Tut-ankh-Amen Col. William Boyce Thompson secured some ancient Egyptian seeds with which he will experiment at his laboratory on his estate at Yonkers, N. Y. He believes that after proper experimentation he will be able to reproduce some of the plants and flowers of ancient civilization.

According to the Pennsylvania Bureau of Plant Industry the rose bug can be successfully fought by using a sweetened arsenate of lead by applying to a gallon of water one ounce of powdered arsenate of lead, and two or three tablespoons of molasses. This is to be applied just before the rose bug appears.

A Hawthorn, over one hundred years old, was recently moved from the center of the city of Harrisburg, Pa., to the home grounds of R. S. Shoemaker in the suburbs. The tree had to make room for a new building, and Mr. Shoemaker considered it worth saving, not only because of its beauty but for its age and history.

It now seems likely that when the Sixty-eighth Congress convenes next December some definite action will be taken providing for the removal and enlargement of the U. S. Botanic Garden at Washington, D. C. Senator Pepper, chairman of the Senate Library Commission, which has the jurisdiction of the beautification of the Capitol grounds, is much interested in the project. He is supporting Director George W. Hess of the Gardens in what he is seeking to obtain to make it rank with the foremost of its kind.

A new potted plant, exceptionally well suited for Winter growing and possessing great possibilities, was recently exhibited by

Dr. F. V. Coville, botanist of the Department of Agriculture. The new creation is a miniature *Rhododendron* grown from seed under glass, and is interesting because of its small size. The plant exhibited (in a six-inch pot) was a little less than two years old, and approximately eight inches high. Dr. Coville explained that it flowered well in pots, the blossoms being about the size of those of the trailing *Arbutus*. Those on the plant were of a delicate pink color and were quite plentiful. The leaves are small. The plant, called the Mayflower *Rhododendron*, comes from the mountains of southwestern China, and has been in cultivation in Europe, especially in France and Germany, for several years. It is quite hardy.

L. A. Hange.

To raise funds for Prevention of Cruelty to Children Society, prominent Westchester County, N. Y., residents will charge fifty cents admission to their grounds in May and June. Among others, Greystone, the estate of Samuel Untermyer at Yonkers, N. Y., will be opened to the public.

Comments from Our Readers

In your article "In the Garden and in the Greenhouse" of the April number, you ask information of the poem which has ever been a great favorite with me. You will find it in the exquisite "Bitter-Sweet" of John G. Holland, published in 1892 by Charles Scribner's Sons.

He makes a master character, "David," say the lines:

"Life evermore is fed by death,
In earth and sea and sky;
And, that a rose may breathe its breath,
Something must die.

Earth is a sepulchre of flowers,
Whose vitalizing mould
Through boundless transmutation bowers
In green and gold."

There are six other gems of verses, to my mind the following one of the most beautiful:

"The milk haired heifer's life must pass
That it may fill your own
As passed the sweet life of the grass
She fed upon."

You would appreciate every word of the book. Very glad to inform you of its wonderful existence.

Larchmont, N. Y.

C. G. McV.

In the April number you have an item in "Things and Thoughts of the Garden" which interests me very much. I, too, dislike the "abominable draperies" and millinery so freely used by some florists in their displays.

You say, "I may be old-fashioned, but I am opposed to giving premiums to lavish displays of ribbons, chiffons, colored burlap, and tissue paper." To me these things mean only vulgar display, an offense against the beauty of nature unadorned.

I wish some one could end that fad.

Westfield, N. J.

A NATURE LOVER.

Department of Book Reviews

The eighth edition of "The American Rose Annual," published by the American Rose Society, should be a treasured volume in the library of every rosarian, professional or amateur. The book contains a fund of valuable information on the most favored of all flowers, and J. Horace McFarland, the editor, is to be congratulated on its compilation, which comprises rose news and notes from practically every part of America. Even if the members of the American Rose Society were to receive no further benefits from their society than the receipt of their rose annual, they are well compensated for their membership.

"How to Grow Roses," by Robert Pyle, now in its fourteenth edition and better than ever, contains advice and information that is valuable to all who grow roses whether for pleasure or for profit. It is well illustrated, the color plates being especially fine. Its chapters tell of the best selection for special sections, of proper planting, pruning and protection of roses, of hybridizing and of own root and budded or grafted roses, in short all that the rose grower should know. The book is obtainable through Conard & Jones Company, West Grove, Pa. Price, \$1.50.

National Association Of Gardeners

Secretary's Office, 286 Fifth Ave., New York

1923 Convention, Pittsburgh, Pa., August 14, 15, 16, 17.

The aims of the association are to elevate the profession of gardening by improving conditions within it.—To cement a closer bondship among all engaged in, and interested in, gardening—to create a greater confidence between employer and employee.

Co-operating with the Massachusetts Agricultural College, the association conducts a course in training young men for the profession, whereby they obtain theoretical knowledge as well as practical experience.

OFFICERS 1923

President JOHN BARNET, <i>Sewickley, Pa.</i>	Vice-President WILLIAM GRAY, <i>Newport, R. I.</i>
Secretary M. C. EBEL, <i>New York, N. Y.</i>	Treasurer MONTAGUE FREE, <i>Brooklyn, N. Y.</i>

TRUSTEES (For 1923)—Thomas W. Head, D. L. Mackintosh, Arthur Smith, New Jersey; Robert Cameron, Massachusetts; Andrew L. Dorward, Rhode Island.

DIRECTORS—(To serve until 1924) William Hertrick, California; George H. Pring, Missouri; Robert Weeks, Ohio; Thomas Wilson, New York; Harold Bryant, Connecticut; Harry Cartwright, Michigan; H. Ernest Downer, New York. (To serve until 1925) George Wilson, Illinois; James Stuart, New York; William Kleinheinz, Pennsylvania; Edwin Jenkins, Massachusetts; Carl N. Fohn, Colorado; Joseph Tansey, New York; John Tonkin, Pennsylvania. (To serve until 1926) Alexander Michie, New York; George F. Stewart, Massachusetts; Theodore Wirth, Minnesota; George W. Hess, District of Columbia; R. P. Brydon, Ohio; William C. Rust, Massachusetts; Charles Schroll, Wisconsin.

LOCAL BRANCHES

NEWPORT, R. I.: Andrew L. Dorward, chairman; Frederic Carter, secretary.
ST. LOUIS, MO.: George H. Pring, chairman; Hugo M. Schaff, secretary.
NASSAU COUNTY, L. I.: James Duthie, Oyster Bay, chairman; John McCulloch, Oyster Bay, secretary.
BOSTON, MASS.: Robert Cameron, Ipswich, chairman; W. N. Craig, Weymouth, secretary.
WESTERN PENNSYLVANIA: Manus Curran, Sewickley, chairman; Henry Goodband, Sewickley, secretary.
CLEVELAND, O.: R. P. Brydon, chairman; Arthur Brown, Cleveland, secretary.

1923 CONVENTION

As the report of the last meeting of the western Pennsylvania branch, which appears on the next page, shows, the Pittsburgh and Sewickley members are actively engaged in preparing for that event, which will take place at the Fort Pitt Hotel, August 14, 15, 16, 17. While your secretary is not at liberty to reveal the secrets, he knows some big surprises are being planned for the visitors, both of an instructive and entertaining nature.

Probably but few gardeners know that some of the largest plants to be found anywhere in America are to be found in and near Pittsburgh. So note the date and arrange your holiday so that you may see some of the mammoth steel plants. Pittsburgh's parks and the country estates near that city have also beautiful specimen plants which naturally come nearer to the heart of the gardener.

A SEVERE ARRAIGNMENT AND AN EVASION

In a recent issue of the *Florists' Exchange* there appeared a severe arraignment of the gardeners relative to professional ethics, which did not pass unnoticed by those assailed, and called for a strong protest. As the *Florists' Exchange* did not see fit to publish the protest received it is here given:

"To the Editor of the *Florists' Exchange*:"

"After the apparently friendly spirit which the *Florists' Exchange* has been manifesting towards the professional gardener, that it would publish the slanderous statement which appeared in the *Boston Evening Transcript*, reflecting on the integrity of the gardening profession, especially after its Boston correspondent had informed it that he had been misquoted, was certainly a most astounding act.

"I have always regarded Mr. Thommen highly, and believed him to be a friend of the gardener, so it seems incredible to me that he would make the accusation he does confess to have made before the committee of the Massachusetts Legislature. The *Boston Transcript* reports him as having appeared before the committee as a gardener. I did not know that Mr. Thommen was a gardener, but I was under the impression that he was formerly engaged in one of the commercial branches of horticulture. In any event, if Mr. Thommen did appear as a gardener, and not as the correspondent of a trade paper, which he now is, he must have created the false impression that he was present as a representative of the profession which was being attacked, while no one was present in defense of it.

"Had I had any notion that such a despicable stunt was to be pulled off, I would not have failed to have been present to defend the gardener and his profession, and to make known that there are many employers who close their eyes to their gardeners accepting commissions, in lieu of paying them a living wage, calculating that the payment does not affect their pockets, but the dealers' profits, and thus I would have shown that the gardener often becomes a victim of circumstance; and I would also have conceded that all gardeners are not "Simon pure," but that there are some black sheep among them just as there are among the politicians who sat in judgment of them.

"While Mr. Robert Cameron in his much discussed paper on the subject did not represent his profession as being 100 per cent perfect, he laid the blame where it belonged, at the root of the evil, and to which the remedy should be applied. As the *Florists' Exchange* thought so well of Mr. Cameron's presentation of the facts as to refer to them again at some length in its issue of April 14, why then did its correspondent not present Mr. Cameron's side of the case before the legislative committee instead of attempting to besmirch the reputation of his profession?

"The National Association of Gardeners, I believe, was the first organization among horticultural bodies to go on record as opposed to paying or receiving commissions, and since then along educational lines has endeavored to minimize the practice. Experience has shown that legislative enactments even 'with teeth in them' never have resulted in accomplishing what they were intended to, and are never likely to. Somehow, the 'teeth' seem to become dull in the setting. Possibly if a somewhat similar policy as that of the Association were pursued by the commercial interests, and a little persuasion injected, something really tangible might be accomplished.

"It will be interesting to learn what justification the *Florists' Exchange* can offer for assailing a body of men who are striving to elevate their profession, and who have already gained the confidence and support of many prominent men and women, the owners of some of the largest country estates in America, in their efforts. The *Exchange* can only uphold its position by demanding of its correspondent that he substantiate his accusation. If he cannot do so, it will prove that it is simply more of the 'loose talk' which at times is circulated on the subject at issue without the least evidence of proof. If the *Florists' Exchange* values the respect of the gardeners in America, it will come forth manfully and publicly apologize for the slur it and its correspondent, for whom it must assume responsibility, have cast on them.

"M. C. EBEL, Secretary,

"National Association of Gardeners."

The *Florists' Exchange* did, however, respond with an editorial of some length dwelling on glittering generalities of the subject at issue, and in which it referred to the above protest as follows: "it has been forcibly brought to our attention by the secretary of the National Association of Gardeners, and by a member of that same fraternity, that we were most derelict in our duty in (1) printing the report at all, and (2) having printed it, in not having come to the defense of the maligned gardeners with denials of their guilt, etc."

As this again called for a reply, the following communication was addressed to the *Florists' Exchange*:

"To the Editor of the *Florists' Exchange*:"

"Why has the *Florists' Exchange* not followed the usual procedure and published the protest which it received from the Na-

tional Association of Gardeners, and not casually refer to it editorially, thereby further misconstruing the position of the gardener and placing his association in a false light through misrepresentation, instead of confining itself to the actual facts as contained in the protest?

"Your statement in your editorial of this week's issue, referring to the secretary of the National Association of Gardeners, is an incorrect one. You have not been criticized for printing any report of the hearings. You were criticized for exulting over the uncorroborated accusation of your correspondent at one of the hearings. You have not been asked to come to the defense of the gardener. He is already ably defended.

"In the name of justice, I now ask that you again publish the editorial comment complained of, which was affixed to the report from your Boston correspondent of the Legislative hearing, and appeared in your issue of April 21, and the protest of the association. Then say what you will in your defense, and let it rest with your readers to pass judgment whether you were justified in publishing what you did.

"Above all, play fair. That is the only favor the gardeners are seeking.

"M. C. EBEL, Secretary,

"National Association of Gardeners."

The *Florists' Exchange* has not had an opportunity to comply with the request contained in the last communication from the association as this paper goes to press, but I trust that it no longer misunderstands my attitude in the matter. I do not now condone, nor have I ever condoned the practice of paying commissions any more than I would condone the practice of maligning a particular craft for offenses that may be committed by a minority of its followers.

It sometimes appears that there really has been something new uncovered about the practice of giving "gratuitously," but it is as old as history itself, for was not our first gardener, Adam, tempted by gratuitous advice? Abuse will never avail much, but as the world grows better and man becomes more enlightened on the difference between good and evil, we may expect to see the evil complained of gradually abated. In the meanwhile, let him who has not sinned cast the first stone.

M. C. E.

Postscript: The *Florists' Exchange*, is out with another vague editorial, evidently preferring to pursue this course instead of publishing our protests and let its readers reach their own conclusions. Its plea for not doing as it was asked to do is, "matters of immediate interest and importance render it impractical."

As to its own defense it states, "we don't happen to feel that we are on trial so must refrain from that also." It concludes its editorial with "we feel that in the interest of progress this subject should be, and is considered, closed."

Silence is golden! But—I wonder whether the *Florists' Exchange* wishes the gardeners to accept its desire to silence further discussion as a confession of guilt on its part though lacking the spirit of fair-mindedness to admit it?

M. C. E.

INTERESTING YOUR EMPLOYER

At this season of the year when Nature presents its most charming appearance and all are enraptured over its wondrous beauty is the time that you should extend an invitation to your employer to become interested in our association as a sustaining member, and to lend his support towards elevating the standard of our profession which means as much to him as it does to the gardener. Sustaining membership dues are ten dollars a year. Approach him on the subject, and if you cannot furnish all the information he may desire, tell him you will have the secretary write him fully.

Your secretary is endeavoring to keep alert to the welfare of the gardener and his profession. He trusts the time is not distant when he may move about more actively and come into more frequent direct contact with the members. Until then the members can co-operate with him to increase the association's prestige through enlargement of its membership by interesting their employers and fellow gardeners who are not yet members.

WHY NOT MAKE YOURSELF KNOWN?

Where are the men who should now be replacing the former well known writers, whose names appeared regularly as contributors to the horticultural press of the past? I know there are many among the younger gardeners who can very ably contribute notes on interesting and unusual experiences, both in the garden and under glass, which would be a departure from the usual staid cultural articles which frequently are mere repetitions of what has oftentimes been written, if they will only make up their minds to do so.

It is not essential that the articles be lengthy to make them interesting. Pithy notes on the merits of particular plants for different locations—ideas which will help to create individualism, and direct to the gardener, as well as to the many gardeners—suggestions

on the use of native species to popularize them in our American gardens—anything which will arouse a greater enthusiasm in gardening, that is what is being sought by professionals and amateurs alike. Readers are no longer as keenly interested in the plant's history as they are to have more of its general adaptability for particular purposes. They like to read of experiments which are proving better than some of the old school methods and they look upon the professional gardener as being best fitted to advise them. That the GARDENERS' CHRONICLE may give to its readers what they most desire, your Secretary asks the gardeners to contribute such notes to their official organ as they may believe will prove helpful to others. They are not asked to do this merely for glory, but they will be compensated for all notes and articles accepted. This request is made to the older as well as the younger gardeners. Address all your contributions to EDITOR, GARDENERS' CHRONICLE, 286 Fifth Avenue, N. Y. C.

WESTERN PENNSYLVANIA BRANCH

A meeting of the members of this branch of the National Association of Gardeners was held in the Carnegie Library, Pittsburgh, on Tuesday, April 17th, at 8 P. M. Manus Curran, chairman, presiding. John Carman, chairman of Publicity; Aug. Frishkone, chairman of banquet; Niel McCallum, chairman of Lecture; William Thompson, chairman of Traffic; David Fraser, chairman of Entertainment; and Henry Goodband, chairman of Programme, with Manus Curran as general chairman, reported and outlined their plans in detail for the National Convention to be held on August 14, 15, 16 and 17 at the Fort Pitt Hotel, Pittsburgh. Judging by the enthusiasm shown by the committees and the plans already formulated the Pittsburgh convention is going to be "something different." This great industrial centre offers many unusual attractions, and a highly interesting programme is being arranged. Louis Barnet was appointed chairman of the Finance Committee. Niel McCallum gave a short but interesting talk on "The Origin of the Darwin," which was much enjoyed by the members present. Our next meeting will be held on Tuesday, May 15th, at the Carnegie Library, Pittsburgh.

HENRY GOODBAND, Secy.

ST. LOUIS BRANCH

The March meeting was devoted to a farewell party to George H. Pring, who departed on April 1st for a collection trip to Columbia, South America. This meeting was largely attended. Mr. Pring stated that the object of his trip was to collect showy flowered Cattleyas such as Cattleya Trianae and Cattleya Schroederi and incidentally other tropical plants for the Missouri Botanical Garden. The trip will take several months, and he will undoubtedly return with a vast amount of experience as well as plants. He was wished a hearty godspeed by those present. Refreshments were served and good-fellowship prevailed.

The April meeting was given over to an illustrated lecture by Hermann Schwarz, on "The Great Out-of-Doors." Mr. Schwarz told about the value of nature study, the need for conservation and gave most interesting life histories of insects, animals and birds. It was decided to arrange for a meeting in the field during the month of May.

P. JENSEN, Corr. Secy.

CLEVELAND BRANCH

The Cleveland Branch of the National Association met at the Alhambra Restaurant on Monday, April 30, at 7 o'clock. R. P. Brydon was elected chairman and A. Brown, secretary. All were very enthusiastic on the formation of the branch here, and anticipate much good to arise from it. For being only the second meeting, the attendance was good. Indications are that each meeting will bring in new members. Three applications for membership in the N. A. G. were favorably passed on at this meeting. Mr. Brydon gave an interesting account of the Directors' meeting in New York, and discussions on several topics followed. The next meeting has been called for Monday, June 18, at the Alhambra Restaurant at 7 o'clock.

A. BROWN, Secy.

NASSAU CO. L. I. BRANCH

We understand that the meeting of the Nassau County Branch held at Westbury, L. I., on April 26, was a successful one with a good attendance and that the discussions were both interesting and lively. This, however, is all the data we have on hand.

Some of the Long Island members no doubt wonder why the GARDENERS' CHRONICLE does not report the meetings of their branch as it does those of local branches located in other parts of the country. We have done everything within our power to obtain reports for publication, and the local secretary promised to furnish us with the reports of the last two meetings in time for this issue. However, they have not been received as we go to press. In all likelihood, with the late season and accumulated work the secretary did not have time to give to his reporting.—EDITOR.

WATER LILIES

Hardy and tender, day and night blooming, should be included in the selection for large estates and public grounds.

In my catalog you will find the largest assortment of varieties and the greatest diversity of colors to be found in this country.

WILLIAM TRICKER

664 Forest Street
Arlington, New Jersey

NEW MEMBERS

Active Members: Henry A. Dombrowsky, Locust Valley, L. I.; Ernest E. S. Fletcher, Afton, Va.; Frederic Heutte, West End, N. J.; Hugh Campbell, Trenton, N. J.; Jack Pyle, Bernardsville, N. J.; Henry Knight, Morristown, N. J.; William J. Bruce, Cleveland, Ohio; Ernest E. Goatley, Cleveland Hgts., Ohio; James Gibb, Cleveland Hgts., Ohio; Thomas Waring, Cleveland, Ohio; A. C. Macdonald, New York City; James Cartwright, Suffield, Conn.; Max A. Elwart, College Point, N. Y.

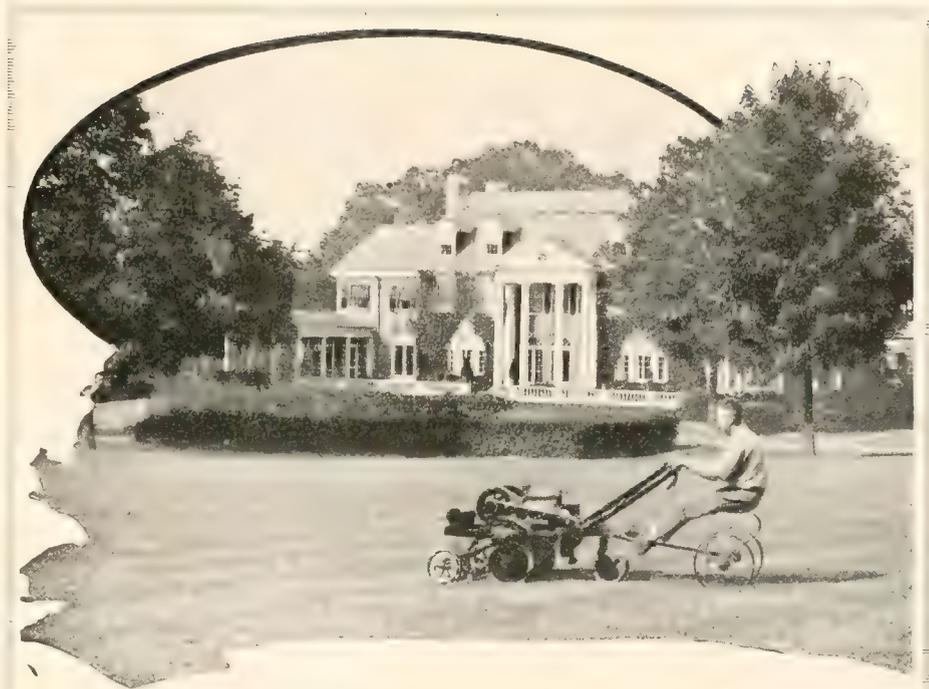

LOCAL SOCIETIES

WESTCHESTER AND FAIRFIELD HORT. SOCIETY

The regular monthly meeting of this society was held at Greenwich, Conn., April 10. One new member, Robert Tickner, was elected for membership and two proposed. The exhibits were numerous and good, Wm. Smith receiving first prize and a cultural certificate for a choice vase of carnations, Princess Dagmar; John McCarroll, second, for a vase of Laddie; William D. Robertson, third, for vase of Benora. Other exhibits included a vase of Laddie and Didiscus from James Stuart; vase of Lilium Harrisii from Wm. J. Sealey; Antirrhinums and Stocks from Ralph Salerno; Antirrhinums from John McCarroll; Sweet Peas from W. D. Robertson; Asclepias Currassavica from Edwin Beckett; Mignonne from H. F. Bulpitt. Mr. Bulpitt also received first in vegetables for some fine bunches of rhubarb.

An illustrated lecture on "Old New England Gardens" will be given at our May 8th meeting by Mr. Underhill, of Boston. Mr. Underhill is well known for his splendid lectures, so all members are urged to come.

It was decided to hold the Fall show along the same line as last year, namely, for the benefit of the Portchester and Greenwich hospitals. The date for the show will be decided on at our next meeting. A note of thanks was given to those members who

MAINTENANCE of a park-like lawn need not be a source of great expense, when one man with an Ideal Power Mower can do the work of from three to five with hand mowers.

The operator need not be a mechanic. An unskilled laborer can do perfect work. Consider the saving in wages and you will understand why an Ideal Power Mower quickly pays for itself even on lawns of medium size.

Write for prices and illustrated literature.

Ideal Power Lawn Mower Company

R. E. Olds, Chairman
431 Kalamazoo Street, Lansing, Michigan
New York, 13-19 Hudson St., Chicago, 11 E. Harrison St.
Dealers in all principal Cities.

Ideal Junior cuts a swath 22 inches wide. Capacity from 3 to 4 acres a day.

Ideal 30" mower cuts a 30 inch swath and mows from 6 to 7 acres a day.

IDEAL Power Lawn Mowers

achieved such splendid success at the recent flower show in New York.

J. G. Curtis entertained us with a splendid lecture on "Plant Feeding." Mr. Curtis is an excellent orator, and had a world of knowledge for us on this subject. His lecture brought considerable discussion. Mr. Curtis answered questions of various members. Other meetings, as instructive, are to be held in the coming months. Every member should strive to be present.—A. K. Cor. Secy.

SHORT HILLS GARDEN CLUB

The Short Hills Garden Club will hold its fifteenth annual show at the Short Hills Club, Short Hills, N. J., on Friday and Saturday, September 28th and 29th. All amateurs are invited to compete, and all lovers of the dahlia, whether amateur or

professional, are invited to be our guests and enjoy the display which every year has attracted large crowds. The dates have been planned to fall directly on the heels of the show of the American Dahlia Society in New York, as the trip to Short Hills is but half an hour, and many from out of town can avail themselves of the opportunity to see the two in one day.

ORIGIN OF PRIMULINUS HYBRIDS

PERHAPS the most wonderful creations of recent years are the beautiful hybrids which have evolved from *gladiolus primulinus*. This remarkable species is found in a wild state in the region of the Victoria Falls, in Rhodesia. It was first discovered in 1887 by Mr. J. T. Last, in the Usagara Mountains, but for its later introduction into commerce Sir Francis Fox was chiefly responsible. It was in 1904 during the construction of the celebrated bridge across the gorge of the Zambesi that this *gladiolus* was rediscovered growing under the spray of the Victoria Falls. The flowers of this species are unique, and were destined to become the progenitors of some of the most remarkable hybrids ever seen. It very soon became popular, and some of the keenest hybridists, both in this country and abroad, quickly realized the possibilities of this African wildling. The charming hybrids which have resulted by crossing it with some of the finer forms of *Gandavensis* have an all-compelling beauty which it is difficult to exaggerate. They are graceful in habit and have all the vigor of the *Gandavensis* type, while the varying shades of yellow which predominate in this race have added a new interest to the *gladiolus* world.—*Horticulture*.

PLANNING THE FLOWER SHOW

VEGETABLE, fruit and flower shows are possible and successful because of the native characteristic in every normal person to enter into competition with his fellow-man, and the greatest good comes from such exhibitions, says the United States Department of Agriculture, only when knowledge and care have been exercised by those in charge of planning the exhibition so that all competitors will be assured of fair and equal treatment. It is often a lack of knowledge on the part of amateur promoters rather than a lack of sincerity that mars the show and makes it impossible for some conscientious competitor to enter the contest, or causes him to be disqualified.

Because of existing demand and an absence of printed information on the subject of show classifications, schedules, arrangement of entries, and other equipment, the Department of Agriculture has published Department Circular No. 62, "Horticultural Exhibitions and Garden Competitions," by M. L. Mulford, horticulturist in the bureau of plant industry, which is intended to furnish a complete and satisfactory guide to those who are contemplating flower shows or who will have the same problems to solve in regard to the coming season's fairs.

The object of horticultural shows and garden competitions is to arouse the interest of citizens and their families, lead them to take a greater interest in such matters, and to incite a deeper study of the best methods of plant growth. Early in the season it is advisable to outline the work for the coming year in order that all may be started on the right track for this year's entries. The circular can be had by application to the Department of Agriculture, Washington, D. C.

THE LONDONERS' GARDEN

A Sussex nurseryman once said: "The Londoners haven't any gardens; this is their garden." He was standing in the midst of the springtide beauty of the fortnightly flower show at the Horticultural Hall, Westminster. A soft breeze waved a patch of fairy-like pale violet primulas set among deep red tulips shading to pink, and sheathed in the softest Spring green leaves.

SOLD BY SEEDSMEN IN CANADA FOR OVER THIRTY YEARS

HAMMOND'S PAINT AND SLUG SHOT WORKS, BEACON, NEW YORK.

Hammond's Slug Shot
Grandfather used it for potato bugs. Father uses it. Mother uses it on her roses.
This year I am using it in my garden.

"HAMMOND'S SLUG SHOT"

Used from Ocean to Ocean

A light, composite, fine powder, easily distributed either by duster, bellows or in water by spraying. Thoroughly reliable in killing Currant Worms, Potato Bugs, Cabbage Worms, Lice, Slugs, Sow Bugs, etc., and it is also strongly impregnated with fungicides. Put up in Popular Packages at Popular Prices.

Sold by Seed Dealers and Merchants.

Wherever the eyes rested were signs of the "Spring o' the Year"—golden daffodils, wide-eyed violets, a glory of azaleas, and hyacinths of every hue.

But it was more than a flower show; it was, as the Sussex nurseryman had said, "a garden." People came not only to admire the beauty, but to study the growth of things. Those who had gardens in the country or even those who had only "back yards" in London, came to get ideas from the results obtained by the expert members of the Royal Horticultural Society.

Garden lovers from all over England and from many other countries were busy comparing this "Londoners' Garden" with their own. They met at the rock gardens, where all the beautiful little Alpine plants showed how the mild Winter had advanced them, and admired the blue of the aubretia on the gray rock with dark purple violas, like wild pansies, on a stone beneath.

Many felt the same about the pink violets. They smelled like violets, but, as one woman said, "One expects them to look 'violet.'"

Nine new plants got the usual attention afforded to any novelty, but a keen gardener aptly explained their position in the show. "There's nothing very particular about them, but then they are new."

There were apples that had just been identified by experts of the society. One had been pronounced a new variety and had been given an award by reason of its good flavor and color. Its fortune then, as an apple, was made, for the recommendation of the society would carry it anywhere.

It is not only at the fortnightly show that problems are put to the society to solve. Every day the society is working to advance the knowledge of gardening for its members. Collectors constantly go to different parts of the world to find new plants. They send the seeds home to be grown at Wisley, where the society has large gardens. Girdling the whole earth is this brotherhood of gardeners for the 18,000 fellows are to be found in every corner of the world.—*Christian Science Monitor*.

He sows June fields with clover, and the world

Broadcasts with little common kindnesses. The plain good souls he sends us, who fulfil Life's homely duties in the daily path With cheerful heart, ambitious of no more Than to supply the wants of friend and kin, Yet serve God's higher love to human hearts;

Giving a secret sweetness to the home.

That never dazzles, and that never tires.

SAMUEL LONGFELLOW.

STATEMENT OF THE OWNERSHIP, MAN-AGREEMENT, CIRCULATION, ETC., required by the Act of Congress of August 24, 1912, of "Gardeners' Chronicle of America," published monthly at New York, N. Y., for April 1, 1923.

State of New Jersey }
County of Union }

Before me, a notary public in and for the State and county aforesaid, personally appeared M. C. Ebel, who, having been duly sworn according to law, deposes and says that he is the editor of the "Gardeners' Chronicle of America" and that the following is to the best of his knowledge and belief a true statement of the ownership, management (and, if a daily paper, the circulation), etc., of the aforesaid publication for the date shown in the above caption, required by the Act of August 24, 1912, embodied in section 443, Postal Laws and Regulations, printed on the reverse of this form, to wit:

1. That the names and addresses of the publisher, managing editor, and business manager are: Publisher, The Chronicle Press, Inc., 286 Fifth Ave., New York, N. Y. Editor, M. C. Ebel, 286 Fifth Ave., New York. Managing Editor, M. C. Ebel, 286 Fifth Ave., New York. Business Manager, D. Ebel, 286 Fifth Ave., New York.

2. That the owners are (give names and addresses of individual owners, or, if a corporation, give its name and the names and address of stockholders owning or holding 1 per cent, or more of the total amount of stock).

The Chronicle Press, Inc., 286 Fifth Ave., New York, N. Y. M. C. Ebel, Summit, N. J. M. E. Bunniston and J. A. Bunniston, both of Madison, N. J. S. Warendorff, 325 Fifth Ave., N. Y. Chas. H. Totty, Madison, N. J. A. Bauer, Deal, N. J. J. Barnett, Sewickley, Pa.

3. That the known bondholders, mortgagees, and other security holders owning or holding 1 per cent, or more of total amount of bonds, mortgages, or other securities, are: (If there are none, so state.) There are no bondholders, mortgagees or other security holders.

4. That the two paragraphs next above, giving the names of the owners, stockholders, and security holders, if any, contain not only the owners, stockholders and security holders as they appear upon the books of the company, but also, in cases where the stockholder or security holder appears upon the books of the company as trustee or in any other fiduciary relation, the name of the person or corporation for whom such trustee is acting, is given; also that the said two paragraphs contain statements embracing affiant's knowledge and belief as to the circumstances and conditions under which stockholders and security holders who do not appear upon the books of the company as trustees, hold stock and securities in a capacity other than that of a bona fide owner; and this affiant has no reason to believe that any other persons, association, or corporation has any interest, direct or indirect, in the said stock, bonds, or other securities, than as so stated by him.

Sworn to and subscribed before me this 11th day of April, 1923.

M. C. EBEL, Editor

HERMAN F. BECK

(My commission expires March 8, 1925.)

ANNOUNCEMENT

A New Department Handling Insecticides

Our Department of Insecticides will provide for both the supplying of standard insecticides in large or small quantities to our customer and the expert advice of an entomologist as to treatment. J. K. Primm, who has been entomologist for the past seven years in government and state service, will be in charge of this Department.

A Short Cut to Its Possession

It is a well known fact that the possession of a greenhouse is a great desideratum for the gardener. The greenhouse is a place where the plants can be protected from the cold and frost of winter, and where they can be kept in a healthy and vigorous condition throughout the year. The greenhouse is also a place where the plants can be kept in a clean and sanitary condition, and where they can be protected from the attacks of insects and diseases. The greenhouse is a place where the gardener can enjoy the pleasure of growing his own flowers and vegetables, and where he can keep his plants in a healthy and vigorous condition throughout the year.

The tribute of James Hurley to Davey Tree Surgery

Brookline, Mass., April 23, 1923.

The Davey Tree Surgery Co., Kent, Ohio.

Gentlemen:

It is a pleasure to me to have this opportunity to express my opinion of your Company, and I have often said to other Gardeners and Superintendents the things I am writing now.

Your men have worked on Mr. Paine's estate off and on for several years, and the work has been entirely satisfactory. In fact, it is the best I have ever seen, and your workmen show a knowledge and skill which I have never seen exhibited by any one else doing Tree Surgery. All the men you have ever sent here were clean-cut, industrious, courteous young fellows of fine character, who could and would do a real day's work without loafing on the job. I do not hesitate to say that Davey men will accomplish more in the same length of time, or for the same amount of money, than anyone else in the business, and whatever they do will be done right. Very truly yours,

JAMES HURLEY.

I have found that "Davey" men, under the supervision of a superintendent needs highly skilled assistance. Many, like Mr. Hurley, protect their trees by Davey Tree Surgery—a science developed by a generation of study and experience. A careful examination of your trees will be

FOR SALE

A Completely Equipped Winter Garden

It is just the right size to fit in your summer garden, to make it an all-year-round one. It is all equipped, ready to start right off growing flowers and fruits. It has been painstakingly designed to make it both attractive and economical to run.

The truth of the matter is, there are a lot of folks right now, who buy enough flowers each year to make their cost far more than the interest would be on one of our glass enclosed winter gardens.

In fact, it's no unusual thing, in such savings,

to have our glass enclosed gardens pay for themselves in a surprisingly few years. Furthermore, you not only have all the flowers you now buy, but a goodly lot of others besides.

What counts with you, is not what the glass garden costs, but how it figures out as an investment yielder and a perpetual pleasure giver. We have some figure facts that you may find decidedly illuminating.

To our printed matter you are most welcome.

A Garden of Perennial Flowers

FIFTEEN BEAUTIFUL PERENNIALS

for \$1.00 POSTPAID

This wonderful assortment includes the most showy perennials and will give a magnificent garden, besides yielding cut flowers bountifully throughout the spring, summer, and fall.

Perennials are easily grown from seed sown out in the open garden during May or June. They will give a gorgeous display of showy and handsome flowers that never fail to attract the flower-lover. Our collection contains one full size packet each of the following 15 handsome perennials:

ANCHUSA ITALICA—Magnificent spikes four feet tall, covered with rich blue flowers during June and July.

AQUILEGIA, LONG-SPURRED HYBRIDS—Graceful flowers in many colors blooming profusely during May and June.

ARABIS ALPINA—The dwarf plants are completely covered with thousands of pure white flowers.

PERENNIAL BABY'S BREATH (*Gypsophila paniculata*)—Tiny white flowers borne on slender stems. Blooms from July on.

CENTAUREA MONTANA—This hardy Cornflower has large, showy, thistle-like, blue flowers.

COREOPSIS GRANDIFLORA—A popular free-blooming perennial with large well-shaped flowers of a rich golden yellow. Blooms during spring and summer.

DELPHINIUM, CHOICE MIXED—Beautiful spikes in shades of blue and purple.

DIANTHUS PLUMARIUS—Star-like, rich rose flowers during June and July.

FOXGLOVE, FINE MIXED—Beautiful spikes in white, pink, rose, etc.

GAILLARDIA GRANDIFLORA—Large, yellow flowers marked with crimson.

GLOBE THISTLE—Thistle-like foliage; large ball-shaped flowers.

HOLLYHOCK DOUBLE MIXED—A complete mixture of the colors.

LYCHNIS CHALCEDONICA (Burning Star) Bright scarlet flowerheads.

PLUME POPPY—A stately border plant 8 feet tall.

SWEET WILLIAM, SINGLE MIXED—Blooms from July on in many bright colors.

These 15 packets of perennials if purchased separately would cost \$1.50. Plant your perennials during the month of June for next year's blooming. The collection will be mailed anywhere, postpaid, for **\$1.00**.

Things and Thoughts of the Garden

WILLIAM N. CRAIG

HOW lovely is early June in the garden! Plants of all kinds have a freshness and beauty which is in a large measure lacking a month later, when the blistering rays of the sun have seared vegetation in spite of all artificial efforts to prevent it. There is a peculiar charm to be found in taking note day by day of the unfolding leaves on trees and shrubs. Many of these have now reached almost their full development, but for the past fortnight it has been a perfect delight to note the springtime beauty of delicate colorings in the unfolding of the leaves. There are not the same rich hues as in the Autumn when scarlets, crimsons, and golden yellows predominate, but the faint browns of the beaches, the delicate greens of the willows, the rich emerald of the horse chestnuts, the ruddy downy leaves of the oaks, the tender greens of the maples, the soft and graceful hues of the larches should appeal to everyone who is at all sensitive to the late springtime beauty of perfection in delicate colorings. One would fain wish for a prolongation of the season when so much is tender, beautiful and good but perhaps this is selfish, for all life must run its course and be finally gathered to its rest. This is, however, no season for narrowing thoughts, far too many garden enthusiasts keep their machinery of dislikes constantly oiled, while 'twould be vastly better if they utilized their powers of praise and appreciation more.

* * *

We have now a fine variety of hardy azaleas adaptable for garden uses, and the newer introductions from China and Japan with one or two home raised hybrids give us a wide range of forms and colorations. I am aware that botanically speaking there are really no azaleas at all, but while botanists may decree one thing the great army of garden lovers are unlikely to change over to rhododendrons, and will continue to think of the latter as broad leaved evergreens, and azaleas in the main as deciduous shrubs. In our colder states none of the evergreen azaleas are reliably hardy and but few of the rhododendrons. Our native azaleas contain some beautiful varieties such as *arborescens*, *canescens*, *calendulacea*, *viscosa*, *nudiflora*, and *Vaseyii*. I think *Vaseyii* is the queen of our native varieties if not of the entire hardy azalea family. It makes a most graceful shrub and the lovely shell pink flowers are of a color which the most fastidious cannot possibly object to.

A number of years ago I had occasion to make a good sized planting of *Vaseyii* on the shores of a large pond; amongst the azaleas, and running down to the water's edge, bulbs of *narcissus poeticus* were planted; also scat-

tered amongst them were clumps of that charming pure white Iris, sometimes called *Sibirica* Snow Queen, but more frequently and more correctly as *Orientalis* Snow Queen; dotted here and there were also some clumps of *Osmunda cinnamomea*. The azaleas and narcissi flower together and the charming soft pink flowers of the azaleas rising above the groundwork of white narcissi forms as lovely a combination as can be obtained. The white iris rather closely follows the narcissi, and the ferns and iris foliage makes a refreshing green right through the hot months. While all of our native azaleas are really woodland plants, they can be successfully cultivated in the open; but at least partial shade will prolong their blooming season and in such a location the flowers will show up much better.

* * *

Of the evergreen azaleas the Japanese *Kämpferi* is undoubtedly the best; in the latitude of Boston this is really deciduous but proves very hardy and never fails to give an abundant display of flowers each year. It succeeds quite well in full sunshine, but shows up to the best advantage with a background of hemlocks or other tall growing evergreens. While this azalea will withstand temperatures as low as 15 to 20 degrees below zero without any injury, the flower buds when expanding are very easily injured, and this season several growers lost all their upper buds when the thermometer dropped just a shade below the freezing point. The old *A. amœna* in favorable locations will winter a little north of Boston and maintain its foliage, as will its varieties, *Hinomanyo*, *Fujimanyo* and *Hinodigiri*. *A. ledifolia* and its pretty lavender colored form, *Yodogawa*, and *A. indica alba* are seen in quite good condition occasionally. The last named cannot be classed as dependable although succeeding very well two hundred miles to the south of us.

* * *

Too many people are still obsessed with the idea that azaleas can only be successfully planted in Spring when, as a matter of fact, they do much better planted in Fall. The Arnold Arboretum which grows azaleas very extensively and plants them with the best possible taste, has made quite extended experiments to ascertain which is really the best planting season for these popular flowering shrubs. Last year thousands were planted out in Fall, many of them just before the ground froze and they came through in splendid condition, even Professor C. S. Sargent, the venerable and esteemed director of that institution, who has always been more or less prejudiced against the Fall planting of trees and shrubs, has seen enough to

JUN 21 1923

convince him that nursery stock of azaleas planted in the Fall succeeds a great deal better than when Spring planted. The Arnold Arboretum, by the way, when it has completed its azalea plantings, will have set out no less than 300,000 of them which should surely present a glorious showing in their season.

* * *

The fact that azaleas do so much better when planted in the Fall should help to kill some of the existing prejudices against Fall planting. Over thirty years' experience in boreal New England has clearly proved that with a few exceptions deciduous shrubs do better planted in Fall than Spring; that rhododendrons transplant very successfully in August; that hardy roses planted about November 1 will easily beat those planted in April or May; that apples, pears, plums, cherries, gooseberries, currants and even raspberries amongst fruits are much better planted in Fall; that nearly all hardy herbaceous perennials succeed far better planted in Fall than Spring; and many evergreens, if carefully planted and properly cared for, will give just as good results if moved during August and September as in late April and May. Nurserymen are simply overwhelmed each Spring and have but little Fall business. There would seem to be no solid reason why these conditions should continue. He or she who buys fruit trees or deciduous shrubs in Spring usually gets stock which has been dug the previous Fall, and has been carried over Winter in storage houses, often the roots are none too damp, and many plants on receipt will present a more or less shrivelled appearance, in no sense can it be compared with stock dug in the open. The growers of nursery stock would much appreciate a longer shipping season and they can only get it when people awake to the fact that Spring is not the only planting season, and that if they would but buy more in the Fall, they would secure better stock and have it delivered much more promptly. Why not plan to relieve the Spring pressure by doing some planting the coming Fall?

* * *

The hybrid rhododendrons are now in their full glory. The past Winter while prolonged was not especially severe and plants almost without exception came through in excellent condition. We hear much about the Winter killing of these showy plants. I am of the opinion that the main reasons why so many plants look miserable in Spring are not so much low temperatures as a deficiency of moisture at the roots, excessive Winter protection overhead, and exposure to biting winds. Young plantings in our colder latitudes need a little protection the first two years until established, afterwards they are much better without it. The removal of coverings of evergreen branches or burlap is invariably carried out when we have one of our premature bursts of heat in March, and the sudden exposure to hot sun, and later biting frosty winds is in reality the cause of the "burnings" of the foliage so much in evidence each season. If these broad-leaved evergreens go into the Winter with dry feet and the ground remains hermetically sealed for weeks, or maybe months, they cannot be expected to come through the Winter well. There is one other menace to successful rhododendron culture in the lace wing fly which is responsible for the deaths of thousands of plants, and the disfiguring of many more. This pest is very destructive to rhododendrons and kalmias growing in full sunshine, but rarely troubles those in the shade. It can be readily controlled by using a good nicotine spray with some soap added. Aphine and other proprietary remedies prove effective; care must be taken to use a fine misty spray nozzle and to direct the spray upwards as the pests work below the leaves and must be hit and suffocated by contact.

The prices of rhododendrons have advanced enormously since the passage of Quarantine 37, but our native varieties like maximum, catawbiense, and carolinianum are still obtainable at reasonable rates. Catawbiense is the parent of our many beautiful hardy hybrids. There is a tendency on the part of landscape men to overplant maximum, commonly known as "the Great White Laurel." It has the advantage of being a late bloomer; the trusses are, however, small compared with those of the hybrids, and I do not consider it in any way comparable with *Kalmia latifolia*, our common "Mountain Laurel," in beauty. Of the hardy hybrids of catawbiense the following have proven very reliable in the vicinity of Boston where rhododendrons have been much planted. *Album elegans*, blush white, a splendid variety; *delicatissima*, white suffused with pink, the finest light colored sort we have, flowers moderately late; *roseum elegans*, rosy pink; *Charles Dickens*, scarlet; *Everestianum*, rosy lilac, sometimes called lavender; *Caractacus*, a reliable purple crimson variety; *album grandiflorum*, a robust sort similar to *album elegans* in color; *atrosanguinea*, dark scarlet; *Boule de Nieve*, of dwarf habit, pure white in color and an early bloomer, good for the front of beds; *C. S. Sargent*, an excellent crimson; *Kettledrum*, deep red; *Mrs. C. S. Sargent*, a lovely pink, and *purpureum grandiflorum*, purple. A number of other varieties have proven hardy but those named give a fine range of colors and should naturally succeed better in sections somewhat less severe than here. If broken from the morning sun, kept well mulched all the time with leaves, and moist at the root, there is no reason why rhododendrons should not succeed well. The one time idea that peat was needed for their successful culture has been long ago exploded, having been abundantly proved that they will thrive just as well in loam. Like other members of the natural order Ericaceae, they cannot be grown in soils containing lime, but scientists are now telling us that it is possible to treat such soils and make them grow rhododendrons and allied plants successfully.

* * *

I have been very much interested in the movement started recently, to collect a fund, the interest of which will be utilized to perpetuate the memory of Jackson Thornton Dawson for over forty years superintendent and propagator of the Arnold Arboretum, the greatest Mecca of living trees and shrubs on the American continent. It is proposed to use the interest from the invested funds for suitable medals or prizes to be offered through the Massachusetts Horticultural Society annually. Probably there has been no more unique figure in the last half century than that of Mr. Dawson, who gave practically the whole of a long and very busy life to the propagation, hybridization, and culture of hardy trees and shrubs. As a propagator he was so successful as to be almost uncanny, and during his lifetime he raised plants simply by the millions which were sent to nearly all quarters of the globe. To the present generation of tree lovers, the genial face and warm hand clasp of Jackson Dawson is very familiar, but it is fitting that a movement of this kind should have been started to keep in fragrant memory one who labored so long and unselfishly for the advancement of American arboriculture. The treasurer of the Jackson Dawson Memorial Fund is Thomas Roland, Nahant, Mass., and E. H. Wilson, assistant director of the Arnold Arboretum and noted plant collector, is acting as chairman of the committee.

In the Garden and in the Greenhouse

GEORGE F. STEWART

IN THE GARDEN

THIS month, late June, and early July, is probably the showiest part of the whole year for the herbaceous borders. Delphiniums will be in all their glory, and I doubt very much if in any part of the year we have a better garden plant. They are general favorites with everybody and of late years we have wonderful shades of color among them. Another thing in their favor is that they can be used with great advantage with several other colors, and at this season of the year delightful pictures of the various groupings may be made. *Campanula medium* in its several colors flowers at the same time and blends well with Delphiniums. A few clumps of the yellow *Hemerocallis* (Day Lily) scattered along the border also fit in well in the picture, and, of course, *Lilium candidum* and *regale*, also *Oenothera* (Evening primrose); *Polemonium cœruleum* (Jacob's ladder); *Lupinus polyphyllus* in its several colors; *Campanula persicifolia*, blue and white; and *Viola cornuta atropurpurea*.

A good background of green is necessary to get the full beauty of the various colors, and after all I think a wall built in a sinuous line covered with *Euonymus radicans* is about as good as anything. Behind the wall, trees of a drooping habit may be grown, which, when hanging slightly over the wall, will break the stiff outline somewhat. The plants in the border will need to be kept in position by stakes to avoid breaking down the taller plants by rains and high winds. This requires some experience, and a good eye to preserve the natural appearance of the plants.

The borders require frequent cultivating to loosen up the soil, and should be kept well supplied with water while the plants are flowering. If a succession of flowers is desired all through the Summer, plans should be in mind as to what to fill in with as the other plants go out of flower. Delphiniums, as soon as the flowers pass, should be immediately cut down to the ground, and a little fertilizer worked in around each plant. In this way a second crop of good flowers may be had later on. The flowering season of *Campanula medium* may also be prolonged by picking off the seed bags, as soon as the individual flower passes. All these details require time and labor; but it certainly is worth it in the better appearance of the borders.

Planting out in the beds in the more formal gardens will now all be finished. Keeping the beds neat and clean will, from now on, be routine work. A formal garden never looks well even if the colors are all properly blended, if kept in a slipshod condition. Geraniums should be watered well when set out, and it will indeed be an exceptionally dry Summer if they need any more. By keeping the water away from them, they have a much shorter and firmer growth, and the result is they flower much better. Cannas, on the other hand, require abundance of water, but care should be taken that it is done under the flower stems, as the flowers are very easily injured. Coleus in beds in the formal garden need frequent pinchings to keep them in shape.

Have all the dahlias planted around June 20. They seem to grow well in coal ashes. Divide the clumps to a single eye and cover with a shovelful or two of coal ashes. Pinch them once when about a foot high and apply plant food when they set bud. If given when planted they seem more eager to grow than flower. Dahlias need spraying once or twice to keep insects in check.

This is a good time of the year to increase stock of *Phlox subulata*, pink and white; *Phlox divaricata* with its lovely blue flowers; *Iberis semperflorens*, *Aubretia deltoidea grandiflora*; *Arabis alpina*, *Alyssum saxatile compactum*. There are many places where plants of low growing habit are very useful and pretty in the Spring, and these are all useful in the various positions where such plants are required.

The rhododendrons would be greatly benefited by the removal of all the seed pods if one has the time, but if one has a large plantation of them it is an endless job.

Outdoor roses will now be coming in flower. They require a great deal of watching for the various insects that they are subject to. If a continuous supply of flowers is expected, they must be fed well and given plenty of water. There are now many fine varieties of hybrid teas, but the old hybrid perpetuals have their place and are much more hardy.

Give sweet peas plenty of water, and occasional waterings with liquid manure. Keep the flowers closely picked and look out for green fly. Near the seashore a much longer flowering season may be enjoyed than inland.

Any annuals that have been sown where they are to be grown will need thinning out. If this is not attended to, poor flowers will be the result. Careful weeding is necessary while the plants are small, as they are easily disturbed at the roots. Any plants which are to be moved are better if marked while they are in flower, as one is better able to remember the color of the flowers when placing them in a new position.

If pruning of the later flowering shrubs is needful, do it immediately after they pass out of flower, as if it is deferred until late in the season, no flowers will be seen next year.

Greenfly will be bothersome on some plants and will need dusting or spraying to keep them in check. We find that Imp soap or some of the tobacco solutions does the work, and they are not too expensive.

As soon as one has abundance of peas, it is better to stop cutting the asparagus bed. Give a thorough cleaning and frequent applications of plant food while it is making growth. This builds up good strong crowns for another season. The earlier peas will now be bearing and should have plenty of water. The successional crops as they come in flower are all the better to have a little stimulation with some fertilizer, being given a thorough watering when an application is made. Keep up successional crops of peas. Although in many locations they do not bear well during the hot weather, yet an occasional dish is appreciated by the family.

Celery is an excellent crop to plant after peas. It requires abundance of water while growing, and is better if sprayed with Bordeaux frequently for fungous diseases. On the whole, I think celery is better if planted on the level ground rather than in trenches. It gets a more free circulation of air during the hot weather.

Late cabbage and cauliflower may now be planted out. Secure a nice rich, deep piece of land, on which they have not been grown for some years. Melons, cucumbers, squash, egg plants, are also benefited by spraying with Bordeaux, as they also are liable to attacks of fungous diseases. Don't wait until the plants are affected, as spraying is only a preventative.

Keep up a successive planting of corn well into July. Even if one does get caught with early frosts occasionally, it is worth the risk.

Rutabaga turnips may be sown in July. Blanched tops of this root are enjoyed by some during the Winter and quite a number can be used for supplying the same. Sow more lettuce and endive for succession. These need tying up to secure nice blanched hearts. I mean the Romaine or cos type of lettuce.

Keep the tomatoes tied up. Sometimes egg plants and peppers are also better if given some support. A little nitrate of soda helps the tomatoes after they have started to bear fruit. Onions also appreciate extra plant food, as do parsnips, leeks, etc. By frequent watering in dry weather the soil soon gets exhausted, which will show on the crops if extra plant-food is not given.

Cultivate the potatoes well and keep them sprayed with arsenate of lead, so that the potato bug will be checked before any damage is done.

When the fruit is all picked from the strawberries look out for the strong runners. See that they are layered well to secure good roots as early as possible for transplanting.

The currant bushes also need attention after the fruit is picked. Cut out the old woody shoots so that the young wood will have a chance. This also applies to gooseberries.

Outdoor grapes thrive better if a few leaves are stopped ahead of the bunch. Any loose shoots should be tied in.

Apples need to be watched for any outbreak of late hatching caterpillars, and sprayed to prevent damage to the foliage. The fruit is all the better to be thinned out, removing the unshapely and poorer fruits, and if any part of the tree appears to be too crowded with branches, it may be thinned out. This is more easily seen when the foliage is fully grown than when leafless in Winter. The wound also heals over more quickly.

Peaches should have some of the poorer fruits removed, saving all the good ones that turn towards the sun. The peach borer is the worst enemy of the peach. It may now be controlled by using Para-dichlorobenzene. The trees, however, must be over four years old before they are practiced on, but it is said to do damage to apple trees, so that it is better to be careful and take no chances.

IN THE GREENHOUSE

With all the beauty of outdoor borders at this season, let us not forget the greenhouse, as the foundation of many of our next Winter's flowers is laid at this time. Young roses should be planted by the last week in June. The benches are better if emptied a day or two to give them a good, thorough cleaning. There is nothing better than a good painting on the inside of the bench with hot lime, which is an excellent disinfectant and makes a sweet foundation for the new compost. The compost should be a good, rich, strong loam. If a little clay is in it, so much the better. Plant the young plants firmly and place the wires in position so that a tie or two may be given. They need syringing every bright day, but all foliage must be dry before night. On carried-over plants, we dry them off just sufficient to clear out a good deal of the old soil, right down to the bottom boards. Cut them down to a foot above the bench. I am not a believer in drying carried-over plants severely before pruning back, for in my experience they are harder to start—root action being destroyed a good deal by severe drying. Our plants have their foliage quite green when they are cut down. From my observation they start much stronger eyes. We have carried the same plants for seven years, and had as many flowers the last year as the first. It all depends on the treatment they are given.

Young Carnations do better if benched as early as possible, especially if good length of stem is expected in the Fall. They are more easily controlled as regards insect pests indoors. It stands to reason also that when they are

lifted in the field, after they attain considerable size, their root action receives a severe check, which takes some time to overcome. The result is short-stemmed flowers for a first crop in the Fall. Give all the air possible in the carnation house, also moisten the floors and under the benches during the hotter part of the day. Let the plants get a little on the dry side before watering, and then give the plants a thorough syringing, making sure that there is plenty of time for them to dry off before night.

Keep a sharp look out that young begonias do not get too well rooted in the small pots. Move them along, and keep them growing, if plants of fair size are desired. Good fibrous loam, flaky leaves, preferably oak, and decayed cow manure in equal parts, adding a fair sprinkling of charcoal, is what they like to grow in. Keep them well up to the glass, and have the house in a good moist condition, never letting the plants get dry. There are no more handsome plants than well grown specimens of the tuberous rooted *Socotrana* hybrids.

A batch of poinsettia cuttings should now be rooted. Pot each cutting in a mixture of finely sifted sphagnum moss and sand, adding a little finely powdered charcoal. Set them in a tight case, and water every bright day, until they show signs of rooting. Air the case out for a few minutes, two or three times a day, and you will hardly ever lose a cutting.

Euphorbia Jacquinæiflora is one of the showiest and most useful plants that flower around Christmas, and later. They are easily rooted if not over-watered. We have had good success by placing them in small pans in sand, and watering them well. Then we set them on a shelf near the glass in a warm close house. Do not give them any more water until the sand gets quite dry. By this method, they will root in a month to six weeks.

Don't neglect the *Hippeastrums* or *Amaryllis* plants. Feed them well, and get a good strong growth by placing them on a light bench until their growth is complete, or the chances are that you will not get them to flower well next Winter.

Select a cool shady position for the young *calceolarias*, *cinerarias* and *primulas* during the hot weather. A frame on the north side of a building or wall, if one has not a greenhouse facing north, is the best place for them until Fall.

Antirrhinums intended for flowering next Winter should now be ready for potting off. It is better not to pinch them until they show a flower bud. They then break strong from the base of the plant, furnishing later on those strong stemmed spikes of flowers which we all delight to see.

If the greenhouses are crowded, cool hardwood plants may be plunged in ashes outdoors. They should be gone over several times a day, to make sure that they do not suffer for want of water. Syringing on all bright days is also essential for them. When growing well, feeding is also in order, until they set their flower buds. Weak cow manure water and Clay's fertilizer, we find agree with them, and after they have set bud, soot water gives added lustre to foliage and flowers, and does not excite the plants into growth.

Nerines will now have finished their growth, and to make them flower well they need a thorough baking in the sun. We find that the nearer the glass they are, the better they will flower after they are ripened.

Palms will require plenty of plant-food, especially if they have not been potted recently. Give all ferns plenty of room to develop their foliage, and have a free circulation of air through them. This is necessary, especially for *Adiantums*, and other fine foliaged species. If they are crowded, they are apt to get brown in the centre. Avoid too heavy a shade over them, just enough to break the

strong rays of sunshine. They will grow much hardier and will last better when the time arrives to use them.

Eucharis Amazonica, which show signs of having completed a set of leaves, may be dried off somewhat, and as soon as they indicate the least desire to throw up a flower stem, water and feed them well. To flower well, they like to be considerably root-bound.

Many of the *Cattleyas* are now growing vigorously, and need plenty of air and moisture. Be sure that they are not over-shaded. This is especially true of the *Gigas* section, which will not flower unless they get all the light possible. The earlier *Calanthes* are rooting freely, and may now receive weekly applications of manure water. They grow best close to the glass, in a warm, humid atmosphere. *Dendrobiums* also, when making their growth, like plenty of heat and moisture, but should only be lightly shaded. *Miltonia vexillaria* will be passing out of flower, and should not be over-watered, until the new growths begin to emit roots. A sharp lookout for insect pests on all the orchids at this time of the year is necessary, as under warm humid conditions they breed fast.

Early fruit will now be ripe, and all the air possible is necessary. When pot fruit has been harvested, plunge them outdoor in ashes, and syringe and feed them well. After the crop has been picked on peaches and nectarines indoors, give them a thorough watering and syringing, and thin out any overcrowded parts of the tree. The late grapes will be past setting their fruit, and thinning will be the order. Don't be afraid to give the berries plenty of room. Be sure and not over-crop, twenty-five pounds to a rod of say twenty-five feet in length is safe, if in a healthy condition. A good application of Clay's fertilizer after they are thinned, will help considerably. Loosen the soil on the surface of the border and give abundance of water.

SWEET-SCENTED GARDENS

Light and shade, good form and pure color, are desirable in the garden, but, though less evident, the best of leafy and flowering plants that possess a sweet or graceful perfume are also enjoyable. Evergreen shrubs, like Sweet Bay, Lavender, Myrtle, and Rosemary are valuable for sheltering hedges, or for sheltered nooks and corners near the house, especially so in mild and sunny localities near the sea. Of all seaside shrubs in flower none, perhaps, surpass the *Laurustinus*, as now covered with its clusters of snowy blossoms. There are three or four varieties of *Laurustinus*, all beautiful and free blossoming, but perhaps the one with glossy leaves is the most beautiful when seen in flower. The plant is an evergreen also, which is another advantage, and the perfume of its flowers is fresh and healthful. Every garden, even a road-side cottage garden, may boast of its sweet-scented Mezereon bush, its Rosemary, Lavender, Roses, Sweet Briar, Pinks, and Carnations, with its Violets and Pansies beside the Box-edged path or on each side of the door.

It is true we cannot boast of our Lemon and Orange groves, but our climate is still kind to many fragrant things—to Honeysuckle, Virgin's Bower, Jasmine, Sweet Verbena (*Aloysia*), Magnolia, and to Cherries, Plums, and Hawthorn. In bed and border alike we may grow hosts of beautiful and fragrant things—Woodruff, Pinks, Balm, Musk, Violets, Rockets, Primroses, Wallflowers, Carnations, Stocks, Sweet Pea, Mignonette, and many other plants that "distill sweet odors on the evening air." We have known outside Vine borders coated with fresh earth and manure every year, and then carpeted with Mignonette and Night-scented Tobacco, give delightful results. In one place we know the narrow borders be-

neath the windows of the house are sown every Spring with Mignonette and Night-scented Stocks, which fill all the lower rooms with fragrance if a window is opened. On another large house every spare inch of wall below the bedrooms is trellised for Magnolias, Tea Roses, Jasmine, Honeysuckle, *Chimonanthus*, and the Sweet Clematis, or Virgin's Bower, and from June to October *Heliotropes*, *Violas*, *Verbenas*, and scented Cape *Pelargoniums* are planted in the flower beds below.

When we consider our glass-roofed gardens and plant houses, there is practically no limit to the sweet things, both leafing and flowering, that we can grow. The scented *Pelargoniums* and many beautiful plants and bulbs bring us the perfume of the Cape or the desert to our doors. Orchids of all kinds, odorous, from the tropics and mountains of both east and west, the *Gardenia* and *Tuberose*, the *Eucharis Lily*, and tropical flowers of a hundred kinds exhale their perfume for us, even in our most smoky towns. Of fragrant flowering and foliaged plants we can never have too many in our gardens and glasshouses. It is something to remember that even a cottager may possess a sweet-scented garden around his door, and that no flowers are sweeter, however more rare and expensive to obtain or to grow, than are the wild Violets, Roses, and Lily-of-the-Valley of our own hedges and woods.—*Gardening*.

CONSTRUCTING A FLOWER SHOW GARDEN

FEW visitors on entering a flower show and beholding the wonderful sight that greets them, which is created by the classes for large garden exhibits, have but a slight conception of the amount of work, responsibilities, and heart-aches which are entailed in the planning and construction of these gardens.

First comes the forethought of the exhibitor who must outline in his mind the style of garden he desires to create; after which he secures the services of the architect to prepare the plans and specifications, which are in turn handed over to the mechanics to build the understructure. The foundations of these gardens are not all soil, but often have concealed intricate mechanical contrivances to produce some artistic effect. Note the accompanying illustration of the "underground" construction of the John Scheeper's, Inc., bulb garden at the International Flower Show last Spring, showing the frame work for the rows, plots and garden paths ready for their plant inhabitants. The plants are not merely stuck in as so many artificial things but are treated as living plants must be to survive the period the garden is to be exhibited.

The construction work provided for, thought turns to the necessary plant materials, and after it is liberally estimated how many of the different varieties are required, preparation is made for their forcing, not overlooking the grass for the plots and paths, nearly all of which is accomplished under glass, and the arrangements for which must be made many months in advance of the show.

When the time for the flower show approaches, construction and planting material and all necessary accessories are gathered in the exhibition hall within forty-eight hours of its opening and mechanics and gardeners begin work and continue uninterruptedly until the garden is completed. When the opening hour arrives, a tired but happy group of artisans are found enjoying the fruits of their efforts, while there is not the least evidence to indicate to the visitors the confusion, excitement, and rush of the last hours to bring the gardens to the perfection in which they find them and to whom they appear just as natural as long established outdoor gardens.

In the garden exhibit here described which covered eighteen hundred square feet of space, there were used

*R. Wichuraiana*

Single Roses in English Gardens

ARTHUR T. JOHNSON, F. R. H. S.

RECENT Summers have marked at least one notable change in our English gardens. I refer to the great increase that has taken place in the popularity of the single rose. Some of us had always loved the wild rose, but it was not until a comparatively few years ago that we began seriously to cultivate it, not only by hybridizing but by rescuing some of our fine old standard kinds from oblivion and by introducing new species. America gave us an inspiring encouragement in this direction; Lord Penzance demonstrated the wonderful beauty and adaptability for hybridizing of our wild Briar and then came the glorious *R. moyesii* and the scarcely less lovely *R. hugonis*. These seemed to give the final stimulus to the cult of the single bush rose which is gaining ground with every recurring season.

The peculiar attributes of the single rose, its natural untamed elegance and freedom of growth, together with its comparatively short blossoming season, may not always commend it for use in the formal rosary. But it is often just those very attributes which render it so charming a subject for the semi-wild garden, the border, shrubbery, woodland and many other such places wherein it is without a peer. Moreover, these roses, or most of them, do not demand the careful cultivation of the decorative, or bedding, varieties. They will do almost anywhere, seldom need pruning and, being the real "Roses of June"—the "Month of Roses"—they are the first to herald the advent of Summer.

The earliest of them to bloom in my own garden are *R. hugonis*, just mentioned, with its tall, arching growths wreathed with a multitude of sulphur-yellow blooms, and the brilliant Carmine Pillar. The flowers on this latter are 3 to 4 inches across and of an intense carmine with a white base to the petals. Though nominally a climber, this old variety will do as a bush and is admirable for hanging over a bank. Another early one is the new Glowworm, a very fragrant single in a flaming orange-scarlet which at once suggests a relationship with what is perhaps the most gorgeous single rose in existence, the Austrian Copper. This is a form of *R. lutea*, whose flowers are like goblets of old gold. The Penzance Briars owe much of their beauty to this rare old Eastern species and the well-known double, *Soleil d'Or*, has also borrowed its fine color from the same source.

The *Wichuraiana* singles naturally come under another class, one in which American hybridists have done wonders, but I must reluctantly pass these by with the mention of one and that is *R. Wichuraiana* itself. This delightful little single white is not perhaps as showy as many, but it is one whose creeping habit and fresh evergreen foliage make it so useful as a carpet for rough

banks, for covering the ground at the margins of shrubberies or associating with Heaths and other subjects.

Our native Sweet Briar (*R. rubiginosa*), often more appreciated in American gardens than with us, must always rank high among the wild roses. The best forms are almost as bright in color as American Pillar and, in addition to this and the deliciously scented foliage, the scarlet hips are very attractive. *R. villosus* comes near to the above, but it is of rather shorter stature and the leafage has a greyish tint. *R. arvensis*, in ivory-white, of our woods is one of the few species which does well in shade and it is the wild parent of the well-known Ayrshire roses and others.

R. lucida is a typical bush rose of about 4 feet in height with handsome, glossy leafage which assumes fine autumnal tints. The blooms of *R. lucida* are some 3 to 4 inches across. They open flat and are of a cool silver-pink. Another delightful species, also deciduous, is *R. alpina* whose branches are perfectly smooth, bearing no thorns. The emerald foliage of this bush is adorned with bright rosy-red flowers in early Summer. *R. Pyrenaica*, dwarf and with prickly branches, is a form of the above and this makes a good companion for the charming little *R. nitida* and *R. berberifolia Hardyii* whose yellow flowers have a crimson blotch at the base of each petal like a Cistus. This needs a warm, sunny place, as also does that curious and pretty garden form of the same species, Hebe's Lip, whose creamy-white flowers have a Picotee-edge of red.

We grow the Burnet rose largely on dry banks of porous soil where few subjects do well and some of the Californian species also prosper in such conditions. The former is of course *R. spinosissima*, a native of our sandy wastes and parent of the Scotch Briars. Some of the creamy-white and yellow forms of this species are exquisite little shrubs, very hardy and content, and there are a few choice kinds in pink, one of which is the bronzy-foliaged, very dwarf, William III.

R. macrophylla is a fine, hearty species allied to the Ramanas (*Rugosas*). Like the latter the foliage is handsome, the blossoms very large and followed by conspicuous fruits which remain on the bushes well into the Winter. Of Chinese introduction, however, *R. moyesii* must claim premier place. This makes a vigorous, thin-habited, sturdy bush of some 6 to 7 feet in height, and soon after the pale emerald foliage has appeared the gorgeous flowers unfold. In color these are a deep and velvety blood crimson with a bold mass of stamens in a rich yellow, the petals are of remarkable texture and these flowers, pro-

The illustrations are through the courtesy of Bobbink & Atkins, in whose catalog many of the varieties named are listed.

duced singly, are followed by extremely handsome bottle-shaped fruits.

Though naturally a climber the Musk Rose (*R. moschata*) will, if given space, grow into a large mound with splendid effect. The enormous trusses of blossom borne by this Himalayan Briar are white and they emit a powerful musk-like odor after rain. This is also known as *R. Brunonis*. Another rampant grower, which will also make a huge mass of gracefully arched branches, is *R. polyantha*, of which there are many forms among the climbers. Yet another rose species to which we owe much—perhaps more than any other, in the creation of

R. Lucida

decorative garden roses—is *R. indica*. There are some very lovely varieties of this, one of which bears the name of Miss Lowe, and whose flowers are vivid rose-crimson, being one of the best. Unlike most rose species *R. indica* will blossom at intervals the season through.

If a little tender the milk-white, highly scented, *R. bracteata*, with very large, cup-shaped blooms, is an excellent species. It may at once be distinguished by the size of its bracts which almost surround the orange-red, silky fruits. *R. sericea*, very unique in the possession of its four-petaled blossoms, shaped like a Maltese cross, always strikes an unusual note in the garden, as does that curious form of the same species, *R. pteracantha*, with the fierce, blood-red spines which give the branches a winged appearance.

Among the newer singles of garden origin there are some remarkably lovely varieties and roses of this class, as I have inferred, are becoming increasingly prominent as a feature at all our great shows. One of the finest of these is Ethel James, a strong bushy grower with pure white, fragrant blooms. This novelty might be described as a refined Isobel, and those who know the latter will understand what that means. Mrs. Oakley Fisher is a single in a rich orange-yellow, somewhat after the style of Lady Hillingdon, a good and shapely grower in bush form. Golden Emblem, a magnificent yellow with immense blossoms, has recently attracted much attention, and as much may be said of The Queen Alexandra rose, an intense scarlet-vermilion with a buff reverse to the petals which suggests a single Juliet, doubtless owing to a common parentage in the Austrian Briar. Princess Mary has very big flowers which open flat, a brilliant crimson-scarlet, and close rivals of this splendid variety are the wonderful Red Letter Day and K. of K.

So one might continue, and though I have not touched the fringe of a vast subject, enough has been said, I hope, to indicate the drift of our fashion in the modern rose.

Nor is this a mere passing fancy. This type of rose has come to stay. Even our National Rose Society, most conservative of institutions, has at last been forced into a more generous recognition of the single flower. Indeed, the time is not far distant when those responsible for what one may call organized rose culture must accord the wild and other single roses a welcome not less hearty than that already accorded the doubles. It is a question of either doing that or ceasing to be representative of the best and truest side of modern rose growing.

BURNING OF EVERGREENS

EVERGREENS burn much worse some seasons than others. It is not so much the cold that causes this as the increasingly powerful rays of the sun in Spring. Evergreens are unlike deciduous plants; the latter do not mind a period of partial dryness at the roots in Winter, as they are in a dormant condition and have no leaves demanding moisture.

The writer has seen thousands of arbor-vitæ and

R. Hugonis

junipers dead in Spring in the fields where they grow wild, following a Winter which started with the soil dry and when the soil remained frozen for months. The same holds true of nursery stock.

Evergreens must have moisture for their foliage all the time. If it were possible to soak every evergreen just before Winter set in, we could rest assured that the mortality rate would be enormously decreased. This is especially true of evergreens which have not been planted long. Bitterly cold winds will cause some burning, but rarely death if the ground is moist. The planting of windbreaks of spruce, pine or other robust evergreens in nurseries protects plants much and greatly reduces scorching. Windbreaks and moisture would entirely eliminate burning of all but the more tender varieties. If the ground is dry in late Fall, make a ring around as many plants as possible and soak them; push back the dry earth after the water has passed out of the basin. This takes time, but may save thousands of dollars' worth of evergreens in Spring.—*Florist's Review*.

Growing Roses Under Glass*

THE essential requirements for the successful cultivation of roses under glass are good houses, good soil properly fertilized and good plants intelligently treated.

The subject of loam is important, and yet this has often been given too much consideration, while other things, such as water, air, sunlight, bacteria, moisture, temperature and other factors and conditions have been neglected.

I have seen roses growing on a greenhouse bench in two inches of loam that produced flowers which took a first prize in a national rose show in this country. I have grown roses indoors for nearly forty years and have never yet had a rose soil, so called, to work with. This is true of many growers, and yet they produce plenty of good flowers and plants. The important thing is to know how to use the soil at your command so as to get the best results from it.

The best soil is a peat medium, which carries the bacteria, mixed with heavy loam and dry, pulverized, yellow clay. When you have selected the spot from which you wish to use the loam, it should be plowed, in the Summer or Fall before wanted, if possible. Then, if the soil is inclined to be sour, it should be limed and then harrowed. Use hydrated lime for this purpose and not carbonate. Carbonate of lime or limestone gives off fresh carbon dioxide too quickly and is likely to kill some of the bacteria in the peat. Afterwards you can cart on the manure, and, last of all, add the bone meal or acid phosphate, working the ground over in the meantime with the plow and disk harrow until the whole is cut up and thoroughly mixed. Allow the loam to lie out and bake in the sun between turnings-over. At the final working, hill it up with the plow so as to leave it in ridges, where it will bake and heat, starting the fermenting process.

The action of lime is threefold: Mechanical, chemical and biological. It renders clay soils more friable, and it compacts loose, sandy ones. It decomposes organic matter and promotes nitrification. It increases the power of the soil to fix ammonia in the form of nitrates. It neutralizes sour soil and prevents the formation of poisonous compounds.

The mechanical condition of the soil is important, and it should never be worked or handled when it is wet. Some people advocate the use of a drier to dry the loam, but I think this would be too expensive an operation; besides, Nature's way is the best. Let the sun and air do the work, and select a dry time for getting it into the house. If needed for Winter use, pile it up in the Fall and cover to keep dry.

A chemical analysis will tell you how much of certain food elements a soil contains, but it does not show how much of this quantity is in an available state for the use and growth of the plant. We must observe and experiment unless we are well acquainted with our soil. A fertile soil is one that has the power to produce crops. A soil may possess an abundance of the materials requisite for plant growth, but if they are locked up as insoluble compounds, they might as well be absent, so far as we are concerned.

Fertilizers have often been a stumbling block and have probably caused more failures than any other thing. A fertile soil may be kept fertile by giving back to it the ingredients removed by the crops grown on it. Most of our soils are deficient in phosphorus, and it is almost impossible in general practice to apply too much of this element to the ground outdoors. Inside, with ordinary

care, either bone meal or acid phosphate is safe to apply. Either of these should be worked into the soil before planting and they may also be used as a top-dressing during the growing season. They may be mixed with the soil in quantity sufficient for the season's growth, as they combine with the soil and do not leach out, as do nitrogenous manures. We have used acid phosphate for a number of years with good results. It costs less than bone, contains almost as much phosphoric acid and is more quickly available.

Another element that is deficient is nitrogen, and we find that nitrate of soda is particularly valuable on our soil, when we require a quick-acting stimulant. This should be applied sparingly as a top-dressing; it should be crushed fine and may be mixed with equal parts of fine, dry loam to insure a thin coat. It will not exhaust the soil if other ingredients are added as required. Nitrate of soda is good for certain soils that are naturally deficient in carbonate of lime, differing in this respect from sulphate of ammonia, the continued use of which under such circumstances would make the soil more acid.

The nitrogen in nitrate of soda is more valuable than the nitrogen in barnyard manure, as it is more quickly available. Ordinary barnyard manure contains about ten pounds each of nitrogen and potassium per ton and only about two pounds of phosphorus. The content of the latter element is low, because the animals use this up to make bone and milk. It will thus be seen that phosphorus is mostly needed to supplement organic manures, and acid phosphate spread liberally on the manure as it is made and carried from the barn helps to make up the deficiency. The liquid should not be separated from the solid or allowed to run to waste; the urine contains nitrogen, but is practically devoid of phosphoric acid. The soluble nitrogen compounds are wasted in the drainage from the manure pile.

The value of a commercial fertilizer depends on its available content of the elements lacking in the particular soil on which it is to be used. The high-analysis fertilizers are more economical than the low, for the reason that the cost of mixing, bagging, freight charges and all expenses are relatively greater in the low grade than in the higher.

Sulphate of ammonia is the most concentrated of all nitrogenous manures in common use. It should never be used with any mixture containing free lime, for the reason that when the base, lime, comes in contact with an ammonium salt, the sulphuric acid changes its old base, ammonia, for the stronger base, lime; sulphate of lime or gypsum, which is noxious to plants, is formed, and ammonia escapes as a gas and is lost. Neither should lime be used at the same time with bone meal or with acid phosphate, as in this case the phosphoric acid is rendered insoluble. The less the lime content in acid phosphate, the more water-soluble phosphoric acid it contains.

After we have carefully prepared our loam and filled the beds or benches, we are ready for planting and none but the best plants should be used. Select those varieties that do best with you and then use only the best plants that you can get in those kinds. Our experience is that in light soil grafted stock is decidedly superior to own-root, and we shall not plant any more of the latter. The grafted gives us much greater returns. Water well after planting and then use care for a time not to get the plants too wet. It is best to water early in the morning, although in the heat of the Summer watering may also be done in the evening. Spray frequently in hot, sunny weather, but omit this on damp, cloudy days. After the plants are

established and growing well in the Summer time, it is almost impossible to overwater them. Cultivate them by hand, rubbing over the surface of the soil about once a week for the first six weeks after planting. After this time, the plants are generally ready for a mulch of manure, or manure with loam in. Before this is put on, you may sprinkle with bone if you failed to get enough into your soil at planting time.

The regular routine work, such as syringing, fumigating, tying, pinching or disbudding, should be faithfully attended to, to get the best results. Ventilate early in the morning, commencing as the temperature shows the first sign of rising. In the hot Spring months this is especially important. Avoid letting the house get hot early in the morning and then giving a great deal of air to cool it off. This is a sure way to get mildew and the best preventive of mildew is early morning ventilation. The more air we can give on all sunny days and the better we can keep up the required temperature, the better results we shall get. Some of you may have had a nice, new house, as tight as a drum, and yet have not gotten as good results in it as you did in a house not so tight. We ventilate to regulate the heat and to supply our plants with carbonic acid, of which there is said to be twenty-one ounces in every square foot of the air overlying the earth's surface. It should be remembered that this is a constant quantity, and is far in excess of the plants' requirements. It would seem, then, that if we give too much air on cloudy days, when the plants cannot assimilate the carbon, we may do damage, but in greenhouse practice it happens that on sunny days we naturally have to give more air than on cloudy ones. It is a point worth remembering, and it is well not to overdo the fresh air in dark weather, when the plants cannot assimilate it.

Failures in rose growing are more often due to lack of attention than to lack of knowledge. Do not make the mistake of trusting to one idea or jumping at conclusions, or considering one point all-important. On benches, too much water carelessly applied at one time will wash away and leach out much of the nitrogen, whereas on solid beds there is some possibility of recovering a part of this by capillary attraction.

We have now a wonderful lot of roses to grow. New ones are being sent out this year, and we are promised still more for next year. Great strides have been made. I do not think that we shall ever see the perfect rose. I rather hope not, for it seems that if we ever attained perfection, there would be an end of all endeavor, and the joy of trying out new varieties would be at an end.

The four great principles of plant life are absorption, assimilation, evaporation and propagation, and in the proper functioning of these depend the life of the plant and our returns.

Plants absorb carbonic acid through their leaves, through the influence of sunlight. They absorb through their roots the moisture of the soil and water saturated with the soluble mineral elements which the plant needs through the capillarity of the root system. There is no such thing as the roots absorbing solid matter. They absorb what they can, or what they require for their sustenance, and give off the balance by evaporation, besides making the flowers for our commercial benefit.

However, the soil must be in the right physical condition to promote the growth of the nitrifying bacteria and must have a medium for carrying the bacteria. Peat is a good medium for this purpose. It must have water, air, warmth. A temperature of 75 to 100 degrees is best for this purpose; this tells us why the Summer time is the time to grow our plants. Get an early start and grow a large plant before Fall, if you want to make any money growing roses. Too much water will exclude the air and

arrest the process of nitrification. I was taught that the nitrification stops when it reaches its limit and then the reverse takes place, the so-called denitrification.

ROSES UNDER GLASS

BACK to the Cotswolds and early days, and the palm for Tea Roses under glass is ungrudgingly given to "Old Jarge," "T' Pa'ason's" gardener in that old fashioned rectory garden on the Cotswold Hills, writes K. Dublin in *The Garden*. The "grinhus" was to all intents and purposes a rose-house, climbing varieties, among which "Glory de John" loomed large, practically covering all roof space. It seemed a case of singleness of purpose accomplishing more than a plurality of talent, for the worthy Rector, whose tastes for following the hounds little pleased the proletariat of the parish prone to stray into the "Methody" fold, leaving him with but few of the faithful to care for, took a liberal share in gardening generally to the end of taking credit for success or blame for failure, but in the "grinhus" "Old Jarge" was "aut Cæsar aut nullus."

DIGRESSING AND REMINISCING.—Certainly as "sextant" "Old Jarge" was invested with a certain amount of ecclesiastical dignity, the more especially as, by the keener critics of his master's theology, he was credited with (or accused of) having a hand in concocting the Sunday sermon. This he did not affirm, yet it was rather suspicious that he never denied it; but there may have been less truth in that than in the report that on a certain Sunday morning only the twain turned up for the service, and when "T' Pa'ason" mounted to the top story of the shaky old three-decker pulpit, "Jarge," handing up the ponderous church key, asked him to "lock up when he'd done, there being no use in his a'waiting." That happened prior to my migration to the Cotswolds in 1873, for the minimum congregation personally experienced (including myself) was seven.

"You may break, you may shatter, the vase as you will, but the scent of the Roses will hang round it still," and fragrant memories gratefully crop up of "Old Jarge's" Roses. He lived with them and for them a long and happy life. That was the time when the brave old Maréchal Niel was in the heyday of youth and beauty, and "Jarge," who managed to secure buds from "T' Squire's" garden (Squire Elwes of Colesborne, father of the late Mr. H. J. Elwes) soon converted them into half-standards potted up for "t' grinhus." Could one ever forget those glorious canary-colored, oval-shaped blooms never seen equalled since, compared with which the now rarely seen Maréchal of latter days is of decidedly degraded rank. No! for the exquisite perfume comes wafted back over years. "Old Jarge" and his Roses were talked of from "Cisseter" (Cirencester) to Cheltenham.

But there came times when good relations 'twixt garden (or rather "grinhus") and house were strained almost to breaking point. Those were the "feeding times" when "Jarge," after soaking the border with rain water from the cistern, followed it up by many buckets of nourishing liquid from the sewage tank, and all the rectory windows on the windward side were kept religiously closed. Another critical period was when "Jarge" "smoked t' grinhus," and the same exclusive method was perforce repeated by the maids. "Zeed old Jarge a scratching hisself in t' grinhus this marning" was the sure and certain sign that he had seen signs of green fly, his "bête vert," on his beloved, and weather permitting, fumigation would follow that evening. So much in sympathy was the old man with the objects of his love and care that was there any signs of their discomfort he was telepathically uncomfortable, too. But, as Dean Hole would have said, he had Roses in his heart.

On Designing a Garden

PERCY S. CANE in *The Garden*

TO plan and make a garden is a pastime that appeals very much to most of us. The love of plants and the soil is a natural one, and the rich brown color and clean, healthy scent of newly turned ground is delightful to nearly all of us. In larger gardens much of the work must be done by gardeners, but true plant-lovers like digging and planting, and the pleasure of seeing the results of their own handiwork.

The gardens of today are carefully thought out, and are generally in their results much more beautiful than was formerly the case. They may be formal or informal, stately or picturesque, as seems most fitting, but whatever the style, one should feel in any garden that its own particular character has been developed in the most effective way.

Whether large or small, any grounds should contain, in balanced arrangement, as many of the different kinds of gardens as the nature of the site makes reasonable.

Of the different gardens that one may have, several may be classed as indispensable. Everyone will wish to possess a rose garden, and almost everyone will want herbaceous borders; while a collection of flowering and foliage trees and shrubs may, in Spring and early Summer, form some of the most beautiful and typically English scenes it is possible to have. Rock gardens are always interesting, and when well placed and well made may be very beautiful. Their site, however, needs careful choosing, for, of all gardens, a rock garden must fit happily into its surroundings, otherwise it is better far to do without it. This may be said to apply to greater or less extent to all types of garden, but a formal garden is obviously designed and made, whereas the appearance of a rock garden should arouse the feeling that it has grown there naturally and that no other sort of garden could possibly be in that place.

It has sometimes occurred to me that a great number of people miss a lot of the pleasure of garden making. They like plants of all kinds, but they like them as separate plants, and often entirely miss the added delight of putting them in their right place in the garden. In working or playing with them, whichever way you like to have it, they should, in fact, be used as an artist uses the paint on his canvas, every bit of form and every touch of color subservient to and helping to make the finished picture. This is the way to use plants, unless you are, or wish to be a collector, and like to see them in straight rows, each plant with every atom of its natural beauty carefully staked away. I think that even collections should be in groups and each group as big as the space allows.

Some people possess a happy instinct so far as the design and arrangement of gardens is concerned. The quality most essential to success in such work and the quality, the evidence of which I have found most often missing in gardens I have visited, is the sense of proportion. Many people realize this, yet I have often been asked to treat a certain area of ground, my client saying "we can go farther if necessary when this is done," apparently oblivious of the fact that to extend the gardens in any particular direction might very probably entail the alteration of every garden already made on that axial line. For the plant-lover the choosing of trees, shrubs and plants is an engrossing task. The choice and use of plants are inseparably interwoven. Certain plants belong to certain parts of the garden, and one feels instinctively that they could only be used in particular places and for certain kinds of planting. Shrubs, especially those of beautiful

habit of growth, seldom, if ever, look well in straight borders, and, generally, the more informal the method of planting the better. As with most other plants, the greater number of shrubs should be planted in masses. To see this it is only necessary to compare the effect of a glowing bank of *Berberis Thunbergii* in Autumn, a stretch of *Cotoneaster horizontalis*, or a foamy mass of *Cytisus albus* or *C. præcox* in flower, or seas of *Rhododendrons*, with single specimens of these same plants dotted in a mixed shrubbery. In fact, the difference between single plants and masses of the same thing is often so wonderful that it is difficult to believe they are the same.

Do not plant uninteresting trees, shrubs or plants. There are so many that are really beautiful that the largest garden could scarcely contain them all, at any rate in sufficient numbers to make the most effective planting. It is a sense, partly intuitive, partly the result of training and constantly observing plants, that tells us how and where to use certain plants and what kinds are best for certain positions.

Quite a large number of plants may be grown under any ordinary conditions, but no one would think of planting the Candelabra Primulas, Japanese Irises or *Myosotis palustris*, for example, or any other moisture-loving plants on dry banks or in any position other than low down in damp ground or near water.

In some way one must always contrive a culminating point, which must be approached with increasing interest. From it one must go to unexpected but lesser features, being surprised and pleased to the limits of the grounds.

Between the house and its immediate terraces and surroundings and this principal feature in any set of gardens there should be a pause, as in a good musical composition one must be prepared for, and lead gradually to the point of greatest interest. It is also interesting to take the best of whatever old work is most suitable, and by judgment and good taste make of it a beautiful adaptation for your own grounds.

Another reason for having gardens as widely contrasting in character as space will allow—and it is wonderful how much may be done in a small space if everything is kept to scale—is that one can grow all, of the hosts of different plants as they should be grown in their proper places. Herbaceous plants, annuals and biennials will be planted in the more formal gardens—roses, of course, in the rose garden, and the smaller-growing trees and most of the shrubs in the more natural parts of the grounds. Do not make the mistake of mixing roses with other things, they are essentially plants to be grown by themselves. As in many other races of plants, there is a harmony in their coloring that, like the Scottish clannish feeling, is for members of the family alone. There are, however, exceptions to this rule, as to most others. Numbers of the rose species, such as *Moyesii*, *rubrifolia* and several others can be used most effectively in shrubberies, on banks and in many places other than in the rose garden.

With the significance that the appearance of most shrubberies gives to it, the word "shrubbery" is a detestable one. The shrubbery walks and gardens in which, as well as shrubs, many of the smaller trees will be included, should be some of the most naturally beautiful parts of any garden. The bright colors of their flowers in Spring and early Summer, the variety of choice they offer for any soil and situation and, above all, the beauty of form

(Continued on page 154)

Plant Aggressiveness

WILLARD N. CLUTE

ONE does not have to possess a garden long to discover that plants differ greatly among themselves as to the ruggedness of their constitutions and the measure of composure with which they endure adversity. Looking through the dealer's catalogue he may imagine that all the treasures there described are equally easy of cultivation but he soon discovers his mistake. One plant will require every art to make it grow at all, while another close by is so enterprising that if unchecked it would soon take the garden to itself. From sad experience we have learned better than to trust our tender young onions, radishes and lettuces in the garden by themselves. They get along very well together, it is true, possessing a sort of well-bred repression that plants long accustomed to the polite society of the garden should exhibit, but the wild plants are of a less retiring disposition. Their motto seems to be "get while the getting is good, and take all you can." There is no danger that our cultivated plants will spread out all over the garden, but there is a very real danger that the garden will spread out all over them.

We have dubbed these more aggressive wild species "weeds" and have in many cases passed laws against them, but this does not seem to bother them much. The only legislation that appeals to them comes from a sharp hoe in the hands of a determined gardener. A weed has often been defined as a plant out of place, and so it is in most cases, but we have yet to discover what it is that enables them to get out of place. First, of course, comes the ability to spread rapidly into any region open to them, and next comes the ability to hold what they have taken. The first is usually accomplished by means of light and easily transported seeds and the second by some method of vegetative multiplication. Plants with easily distributed seeds, however, are not always pernicious weeds, for many such have very little ability to hold the ground against others.

The worst weeds are usually those plants with effective means of spreading in a locality after they have become established in it, especially if they happen to be perennials instead of annuals. In general, weeds have the additional faculty of surviving all sorts of untoward conditions. Our garden plants may perish in seasons of unusual drought or cold but not the weeds. Although they may be reduced considerably in numbers there are always enough left to maintain the hope of the race. They have waged war so long with the garden and the gardener, not to mention wind and weather, that they are particularly resistant. It is doubtful whether anybody ever really got the best of a well established patch of quack grass. He may fight it Summer after Summer until the victory appears to have been won, but here and there, concealed by the foliage of other plants or hidden entirely underground, are certain small remnants that bide their time and as soon as the gardener's vigilance is relaxed, back comes the quack grass again!

Our consideration of what constitutes a weed is often modified by considerations of how much it happens to be out of place. Some plants, though regarded as weeds, show so little hostility to our garden crops that it is hard to work up much of a sentiment against them. A patch of tansy along a country roadside is seldom spoken of in disparaging terms. We look upon it with toleration or perhaps with stronger feelings that are quite akin to affection. It is a reminder of that mythical spot known as "grandmother's garden" in which we mentally culti-

vate all those well known plants with which we have been associated from infancy. In this category, also, comes catnip, and motherwort, and that other familiar plant with fragrant leaves the costmary or bible-leaf, which loves to make fragrant mats in out-of-the-way corners.

It always makes a difference whose ox is gored. The very qualities we abhor in the weeds, we commend in such of our garden plants as possess them. No one ever had a really fine peony that multiplied fast enough and the same might be said of irises and many another. Still, one can have too much of a good thing. A plant may lose its reputation for beauty by becoming too common. This is all that is the matter with the dandelion. If this plant had to be carefully cultivated in order to bloom, we should all want a specimen to experiment with. The toad-flax illustrates the idea very well, for it was originally a denizen of the flower garden and not until it showed a disposition to multiply at the expense of its companions was it thrown out to consort with other handsome floral vagabonds like the crown vetch, the common bell-flower and the tawny day lily. The toad-flax appears to hold a hope that it may again be admitted to the garden and, indeed, occasionally pushes in among its more aristocratic friends, but the crown vetch and the bell-flower have no such aspirations and seem perfectly content to establish the colonies by the roadside where they can see and be seen of all men.

The moneywort is fully as obnoxious as the toad-flax, but by confining itself to the lawn and rooting at every joint, it manages to escape eviction. A related species, *Lysimachia clethroides*, is fully as aggressive but possessing, as it does, a more beautiful truss of flowers and showing a disposition to decorate wet and shady places, is looked on with more toleration despite its tendency to spread into new regions.

It is difficult to say which is the worst, the Jerusalem artichoke in the vegetable garden or the lily-of-the-valley in the flower garden. The artichoke, like the quack grass, is able to come back if any small bit is left in the soil. Some in my garden has been coming back annually for more than ten years. Sometimes it seems to be completely eradicated but it manages to get into shape again by the time vacation is over.

The number of garden plants that spread all too rapidly is a large one. In many cases to introduce specimens into cultivation is to provide one's self with a fairly continuous job for half a lifetime. The lily-of-the-valley, though highly valued may easily become a pest among other plants. If only the true lilies would multiply as rapidly! The dame's violet has a tendency to appear in places where it is not wanted and the day-flower (*Commelina*) is a stubborn fighter. One of the evening primroses, *Fraseri*, takes the ground like the toad-flax and has no right to be included among other flowers.

While aggressiveness is often a good trait, it is restful to come back to those well-settled species, which, with no disposition to spread, still maintain existence for a long series of years untroubled by upstart weeds. The peony, the gas plant, the yucca and many another will come to mind in this connection. They do not have to be kept within bounds; they do not fail to come up each season strong and serene. They are the joy of the gardener and serve to keep up his courage when he is nearly overwhelmed with less deserving species that plan to take the garden away from him.

WATER GARDENING

THAT branch of horticulture collectively called water gardening has for years steadily gained in favor, writes Harry Johnson in *California Garden*. During the past 50 years great strides have been made in the development of varieties so that today one may have lilies of all colors and perfect form. All parts of the world have contributed species, from the frozen lakes of Sweden to the sweltering pools of the equator.

The great check to the uninitiated has been the prevalent idea of the necessity of large ponds. Nothing could be further from the truth. Many enthusiastic growers have their needs fulfilled and for years have had successful gardens with only an old washtub or half barrel sunk in the ground. Could anything be more simple? A single tub or an irregular group tastefully planted will give one a most pleasing and novel garden that will require a minimum of care.

Planting and care are of the simplest. To begin with a tub or half barrel should be secured that is water-tight. This should be sunk almost level with the grade and filled about two-fifths full of good garden loam, the heavier the soil used the better. If you have some well-rotted cow manure one part to two of soil may be thoroughly incorporated with it. A three-inch pot of bone-meal can also be mixed with good results. The lily root somewhat resembles in habit the root of the German iris. In planting it should be placed in a horizontal position and so that the growing point will be flush with the surface. To keep the water clear it is advisable to put about an inch of coarse sand over all. The planting is completed by filling the tub full of water.

It is essential in seeking a location for your tubs to bear in mind that water plants always thrive best in a sunny situation. Planting is usually done in early Spring but may be accomplished at any time except during the Winter.

The after care consists in keeping the tubs full of water and in removing occasionally the dead leaves and litter. It is well to put a goldfish in each tub to keep down the mosquito larvæ and to assist in keeping the water sweet and fresh. If properly balanced the water will never need changing.

The lotus, that flower sacred to the Hindoos, grows very well in tubs giving an abundance of its large, stately, peltate leaves borne on stout three-foot stems. The flowers are very beautiful and have a faint, peculiarly pleasing fragrance. The paper-like petals curve in over the central disk in which are embedded the large olive-shaped seeds. The mature seed pod looks for all the world like the rose of a water can. The rhizome is quite different from the water lilies proper and may best be pictured as two or three bananas strung end to end. They are very brittle and are easily broken in handling. In planting, place the rhizome horizontally three or four inches below the surface and so the growing point is just below. The tub, however, should be filled about two-thirds full of soil as two or three inches of water is sufficient. They should be planted in March and April when the dormant tubers may be had. Pot plants may be set at any time during the Summer. The flowers range from dark pink to light shades and also come in yellow.

Many small aquatics in habit similar to water lilies are well worth growing and serve to give variety. The water poppy is very hardy and the bright yellow flowers are counterparts of the California poppy. It increases by runners like the strawberry.

The number of plants that one may have is legion and all are easy to grow. Water is a very stable element and gives the same growing conditions to plants the world over.

THE NATURALIZATION OF PLANTS

THE naturalization of Spring-flowering plants is worthy of much wider expansion that is commonly practiced. Many of the hardy bulbs produce gorgeous effects in the conventional flower-garden where they serve a useful purpose, but for real garden adornment the most effective of all modes of arranging is to naturalize them in grass. In such situations, when once carefully planted, they provide an annual source of beauty and give no further trouble.

In many country places wide belts of bare grass lie between shrubberies and walks, which frequently never provide bright coloring, but only exist to be roughly mown about twice a year. The charming effects which may be produced on these sites by the planting of Spring-flowering bulbs surpass in beauty any formal Spring garden, however gay. In their natural bed of grass the bulbous flowers look far better than they do with the brown earth of a border beneath them.

Where space permits a long season of color display may be obtained by planting irregular groups of bulbs to follow each other in season, beginning as early as January with the Winter Aconite, and continuing in February with Snowdrops, Snowflakes and Chionodoxas. During March a wide choice of material is available which gives the intelligent planter much scope for beautiful color effects, such as Crocuses in variety, Scillas, Anemone apennina, Grape Hyacinths, and the early flowering Narcissi.

The later flowering Narcissi will provide ample material for extending the season through April and May, supplemented by such beautiful plants as the Dog-tooth Violet and several species of Fritillarias and Ornithogalums, all of which succeed and grow freely in grass. Tulips are seldom seen growing in grass, yet where the soil suits them, and there is no danger of the broad, fleshy leaves becoming injured by overhead traffic, both the species and many of the florists' varieties do wonderfully well in such places, and greatly assist in maintaining color and variety in the display.

Naturally the prettiest results are only obtainable when the grass need not be mown until hay-time. The leaves of the earlier flowering plants will then have completely died down, and those of the later flowering ones will have entered the ripening stage, so that the plant will suffer little from the loss of foliage.

Some of these plants and many others also lend themselves admirably to naturalization in our woodlands. The Winter Aconite is particularly suitable for planting under the branches of trees, where it flowers even earlier than in grass, and develops its foliage while the trees are still naked, covering the ground with a pretty, soft green carpet. When this fades the trees put forth their foliage, and hide the ground until Autumn. Crocuses and some of the Anemones are also very suitable for this purpose, and once established they take care of themselves.

There are many plants which do much better in the shelter of a woodland garden than in the open border. The various Christmas Roses flourish in sheltered nooks, and their flowers are much less liable to become weather-stained.

The beautiful North American *Trillium grandiflorum* loves shade and a moist, free soil in the low-lying parts of the wild garden. These few suggestions refer mainly to Spring flowers in the undressed portions of the pleasure garden, which may also be planted with subjects that will bloom through the Summer and Autumn and a few even in Winter. *Gardeners' Chronicle (British)*.

Every man has his gift, and the tools go to him that can use them. *Charles Kingsley*.

Can Narcissus Bulbs Be Grown In America?

IN the May issue of the *GARDENER'S CHRONICLE*, William H. de Graaff, well known narcissus bulb grower of Holland, gave as his opinion that it will not be possible to grow these bulbs successfully in this country for commercial purposes. Since then our attention, has been directed to some recent statements made by American bulb growers, all of which prove interesting in that they show that time alone will tell what may be accomplished in America in the successful growing of narcissus and other bulbs.

A Florida bulb grower states that while it was at first claimed that good bulbs could not be grown in America, northern florists had to admit their mistake, when they found that southern florists were cutting fine flowers from bulbs of their own growing, and then advanced the plea that while these bulbs were all right in the South, they would not force when put under glass in the northern States. He claims that it has been shown, however, that where bulbs can be grown as a Winter crop, dug in April or May, and given the required rest, they are ready to bloom under glass or anywhere else from November 1 all through the Winter, just as imported bulbs do. Now that it is admitted that southern grown bulbs will force all right, he states it is argued that American growers cannot begin to produce the supply used in this country by the time the embargo against the narcissus goes into effect in 1926.

We think that the Florida grower is a little too optimistic when he states that while the possibility of producing the necessary supply may sound big to a little man who sits in an office, to the big American farmer it looks too small to engage his attention, adding that the American farmers have glutted the markets of the world with everything to which they have directed their efforts. He further states that he plants narcissus bulbs in rows two feet apart so that he can cultivate with a hoe or small tractor, (planting forty thousand bulbs to the acre) and that it would only take about eighteen hundred acres to produce this country's demand. He believes the bulbs he is now growing could not do better anywhere in the world than they do in his section; he is growing Chinese Narcissus, Paper White, Grand Primo, Grand Soleil d'Or, and Winter blooming gladioli. Nearly all these bulbs are said by him to have been growing in his section for forty years and are no longer an experiment, but no market could be found for them as long as this trade was controlled by the foreigners.

A bulb grower of Texas writes of his experience in the Rio Grande delta, stating that while one cannot grow tulips there because they must have a period of cold rest, he has taken once used narcissus and in one year had the same number of marketable bulbs and about twice as many small bulbs to grow another year. He planted Easter lilies, securing wonderful stalks of flowers and one marketable bulb the next Fall, and a lot of bulblets which require from one to two years before they reach the blooming size. He believes that the Rio Grande delta is going to be the section of the United States where our flowering bulbs which do not require Winter dormancy or shade will be grown, because the constant sunshine and fertile soil give them a brilliant coloring, and a sturdy and prolific growth that will carry these qualities to the North.

A California bulb grower writes that the work of growing bulbs in California must be largely experimental until more definite results can be obtained and directs at-

tention to the fact that in Holland, tulips, for instance, may thrive in one patch of soil whereas, almost within hailing distance, there will be soil entirely unfitted for tulip culture, and that this is true of other bulbs. So we can only learn after long experience just where bulbs can be most successfully grown in this country. Narcissus bulbs, he states, are only grown in about two provinces of Holland, and the soil varies so in the different localities that one place may be adapted to the growing of hyacinths while about a half mile away it is not adaptable to hyacinths, but excellent for growing daffodils.

We quote David Griffiths, bulb specialist of the Bureau of Plant Industry, from a recently published article: "We should keep firmly in mind that while there is no doubt that we can grow successfully the complete line of narcissus in this country, there is but little probability of accomplishing the fulfilling of our needs in the next twenty years." We feel that when that time arrives, some of us will no longer be as interested, as we are today, as to where narcissus bulbs can be successfully grown.

ON SEEDING LAWNS IN LATE SUMMER

I READ the article "Seeding Lawns in Late Summer" in the May issue, and wish to add a little comment for your next issue. To my mind there is no question about it that Spring not alone is not the best time for seeding lawns, but it is not the time at all. No lawn should ever be started in the Spring for the simple reason that the thin young stand of grass has no chance whatever to get deep rooted enough to go through the trial season of hot weather. The weeds will soon get the upper hand and the result is waste of seed, waste of labor and lots of disappointment to the prospective owner of this lawn-to-be. Although I happen to be in the south at the present time, I have built and cared for many a lawn in the north and my argument applies to these as well. A well kept lawn is, to my judgment, the outstanding feature of beauty on any country place, no matter how large or how small this place may be. A thorough cultivation (for an entire Summer) of the plot where you intend to build your lawn is an absolute necessity, keeping down weeds as fast as they appear. Incorporate in the soil a liberal supply of stable manure to begin with, and finally have your plot by a heavy rolling, followed by a harrowing of the Scotch type of harrow, ready by beginning of September. Buy your seeds in separate quantities (not in mixture), sow at the rate of 120 lbs. to the acre, two parts of Kentucky Blue Grass to one part Red Top, equal part of English Rye grass and add five lbs. of White Dutch Clover, rake in or use the same fine harrow again and roll heavy. Top dress your stand of grass with bonemeal early next Spring at the rate of 600-800 lbs. to the acre and apply during the early Summer on a rainy day, 150 lbs. Nitrate of Soda per acre. Your lawn is made, and permanent. I have a lawn here on the estate (Great Falls, S. C.) now going through its second Summer of 90-100 degrees Fahrenheit for five months or more and have the prettiest green to be seen anywhere. The only thing necessary besides mowing is a thorough drenching with water occasionally and as we have a hydrant handy I do this with the fire hose. I have not a weed worthwhile and not one dandelion in this lawn today.

Great Falls, S. C.

ANDREW ANDERSEN.

ROSES THAT WILL GROW ANYWHERE

BY selecting some of the hardy types which will grow almost anywhere and under any conditions, it is possible to have roses throughout the Summer which, although they may not be as big or quite as varied in their shades of coloring as the tender types, adapted only to a regular "rose garden," are, nevertheless, entirely satisfactory and will give an abundance of bloom for cutting as well as being beautiful where they grow, writes F. F. Rockwell.

There is a whole class of roses, most of which have been introduced comparatively recently, which are literally as hardy as weeds, and which possess the very desirable quality of flowering more or less continuously throughout the entire season. These roses are known as the "baby ramblers," as most of them are dwarf growing forms of such well-known climbers as Crimson Rambler and Dorothy Perkins.

These roses closely resemble their cousins, the Climbing Ramblers, both as to appearance and in colors. They bear immense trusses of small roses and may be had in great variety of colors: pink, salmon-pink, rosy-pink, dark pink, carmine pink, cerise pink, or brilliant crimson with white centre, ruby crimson, cherry crimson, vermilion red shaded to orange, white or yellow.

So it is possible to suit almost every taste in regard to rose color. Some of them are remarkably fragrant and they may be used to splendid advantage in various ways in the home garden or grounds.

These little Baby roses grow on compact, well-shaped small bushes of from 18 inches to 2 feet in height, and are most effective to use as bedding plants where a solid mass in a single color may be made the keynote for the garden. Or they are excellent for use in borders or where they are mingled in with other garden flowers.

They are unusually prolific in their blooming and will bear continuously from early in the season until frost.

The Baby Ramblers, too, have the added advantage of being extremely easy to grow for they are uncommonly hardy and require no pruning. Removing the last season's flower stems is all that is necessary in that line.

When you are setting out these roses, be careful to put the top of the ball of earth about 2 inches below the soil level.

Among the most popular are the Mme. Norbert Levavasseur, similar in color to the climbing crimson Rambler; Mrs. Cutbush, which carries large clusters of medium sized flowers of a pleasing shade of peach-pink, and which blooms until late in the Autumn; Ellen Poulson, dark brilliant pink, and very fragrant; Erna Teschendorff, especially good for mass planting, beautiful deep crimson; Clothilde Soupert, white shading to deep pink in centre and excellent for bedding; Yvonne Rabier, good variety for massing, white with full double flowers.

The rugosa roses will make themselves at home even in such places as on an exposed bank or near the foundation of a building where most other plants would absolutely refuse to grow. The plants, after they once become established, throw up each year shoots or canes from under ground roots, and thus serve to make a thick, very effective hedge where it is desired to use the plants for this purpose. The foliage of the Rugosa roses is very robust and hardy, and insect and mildew proof, and remains beautiful all Summer long. The large single and double flowers are followed by brilliant red "seed pots" which remain on until well into the Winter. In addition to being so very hardy, the plants require no care in the way of pruning except to cut out the old canes clear back to the ground every second or third year to make more room for the new growth.

The Rugosa hybrids are almost as hardy as the regular

Rugosa, and the list of hybrids now contains many very beautiful varieties.

The Rugosa itself may be had in either the single red or white form, or in a double rose.

The Rugosa rose in a beautiful rosy carmine, which carries single, fragrant flowers. This blooms nearly the whole Summer. Rugosa alba is similar to the Rosa, except that the flowers are white. Conrad Ferdinand Meyer is a beautiful pure silvery pink. This is very hardy, and also fragrant, and has very attractive foliage which makes a valuable ornamental shrub.

THINGS AND THOUGHTS OF THE GARDEN

(Continued from page 142)

tion covering over eight acres of space, and containing exhibits from not only Belgium but France, Great Britain, Holland and other countries, I was particularly struck with the eulogistic references to the wonderful display of ranunculus shown in one of the salons by Dr. Attilo Ragionieri, which appears to have been the real sensation of this immense and well varied show. This giant form of florists' ranunculus carried flowers which are all double "and some were fully six inches in diameter and set on a begonia plant would have passed for very double begonia blooms." We are told that there were not many white flowers, but all shades of yellow and gold, red and maroon, mauve and purple, rose, pink, and almost scarlet. It is to be hoped that the Federal Horticultural Board will permit the importation of some of this new race of ranunculi. Surely they would create something of a sensation at the big Spring shows in 1924. It is too much to expect that these giant ranunculi will have any value in our climate as garden plants, but for gentle forcing purposes there should be a great field for them.

ON DESIGNING A GARDEN

(Continued from page 150)

of many of them, lend themselves in their successful planting to the making of some of the loveliest of garden scenes. The Japanese have the reputation for being supreme in the art of landscape gardening, but our English taste, a taste that is the product of long cultivation, likes, at any rate in its gardens, something that is English in feeling. With the more beautiful shrubs and trees, and it may be a few masses of the stronger-growing herbaceous plants and here and there a great boulder of stone, an artist can make gardens every line of which is a joy to look upon.

To see the most beautiful of shrubs grouping themselves in squares and rectangles, as I have seen them do under the supervision of really skilled gardeners, is something to be avoided. Shrubs should be chosen as much for the beauty of their habit of growth as for their flowers, for in form such planting as this is always lovely, whether the shrubs be in flower or not.

There are too many interesting and beautiful shrubs to attempt to enumerate them in the space of a short article. Be sure, however, to include some both of the upright and prostrate-growing Junipers. The grey-green color of their foliage as well as their beautiful habit of growth makes of them some of the most useful plants we have. Also utilize conifers and other evergreens in any planting of shrubs; they add weight, and, in Winter, will intensify the beautiful tracery of the branches of the deciduous trees and shrubs by the contrast with their own persistent green foliage.

To me the meanest flower that blows can give
Thoughts that do often lie too deep for tears.

—Wordsworth.

Preserve the Wild Flowers—Abolish the Sign Boards

DESTRUCTION OF WILD FLOWERS BY INJUDICIOUS PICKING

L. P. JENSEN*

AT the awakening of Nature in early Spring, when the buds burst open and the first wild flowers appear on the sunny hillsides, we feel the irresistible call of Nature and much of our leisure time is spent in the country, modern conveyances enabling us to go far afield in a relatively short time. Outdoor life is essential to our health and happiness and we enjoy it to its fullest extent, but in our enjoyment, through ignorance of the laws of Nature, we are often destroying and wasting the very things essential for a continuance of this healthful recreation. When we pick a handful of wake-robins, bloodroot or Dutchman's breeches we are not only depriving others of their enjoyment of them, but also prevent these plants perpetuating themselves by seed.

On that account some plants are becoming scarcer as the years go by, until some, such as the lady slipper orchids, wild lilies, gentians and hepaticas, have become so rare that they can be found only in out-of-the-way places, protected only by their inaccessibility. Not only are many plants being destroyed by picking of their flowers, but those growing in the loose soil of the woods are often entirely pulled out when the flowers are picked and the entire plant destroyed. Woody plants, such as the flowering dogwood, wild plum, crabapples, hawthorns and others which produce large numbers of showy flowers, are gradually disappearing from our woodlands, due to injudicious picking. In this case not only a few flowers are taken, but large branches are ruthlessly torn off, occasioning serious wounds, which, owing to their torn condition, cannot heal. Insects and diseases enter the plant tissue through these wounds and soon destroy the plants. Many wild flowers are so abundant in a locality and of such a persistent nature, that picking is permissible, but the following rules should be strictly observed.

Never break a branch off a tree or shrub, but cut with a sharp knife close to the main stem of the plant, making a wound easily healed by Nature.

Never pull or pick flowers; cut them with a sharp knife, thereby avoiding pulling up the entire plant.

Do not pick any flowers without leaving enough for seed and for other persons to enjoy.

Do not pick flowers for a moment's enjoyment, to be cast aside to wither in the sun.

Do not tear off large branches of flowering trees and shrubs for the decoration of your auto on the return journey from the woods; by so doing you are destroying the most charming feature of our natural wilderness.

If you desire to continue the enjoyment of our wild flowers and wish to pass them on to your children, as you surely do, you must help us put a stop to the injudicious picking of them.

*Arboriculturist, Missouri Botanic Garden.

WILL FLORISTS AID TO PRESERVE THE WILD FLOWERS

R. C. BENEDICT*

THE whole problem of wild plant conservation may be reduced to a few fundamentals. There are a considerable number of wild plants whose beauty makes them of interest to the general public. In this connection they are subject to gathering by the public itself and by the florist trade for distribution and sale to the

public. In the case of a large number of these wild plants, the natural stock is sufficient to supply all our present demands. Such plants do not enter in as part of the problem of wild plant conservation. A considerable number of wild plants however, for example many rather uncommon forms and others formerly common but now through collection greatly reduced in number, constitute a problem for the florist and also for the general citizen.

It would be unfortunate to render extinct any wild plant which has beauty and general interest. When attractive plants become reduced in numbers, it is desirable that the collection of the wild supply should be stopped. Naturally it will stop itself eventually, but, in the meantime, regions commonly visited by the public at large may have become so depleted of some of their beautiful plants to supply some distant private estate that visitors to the public domain will be deprived of one of the natural beauties of that region. So much by way of general preamble. Specifically, measures along the following lines have been discussed and in some cases enacted as State laws:

1. A protected list of uncommon plants has been established for the State of Vermont. Collection of these plants on public lands is restricted by the law to two specimens apiece for scientific purposes.

2. Collection on private land with the permission of the owner is specifically permitted as a matter of constitutional right.

3. In another State, Connecticut, the right to collection on private land and to transport within the State region of the State flower, laurel, and some other things is hedged about by the requirement of certain *permit forms* which must be attached to packages for shipment.

4. A law was proposed a year or so ago in Massachusetts to prevent entirely the public sale of the State flower, trailing arbutus, regardless of its source, whether public or private land. This was properly defeated, it seems to me, since the right of the landowner to dispose of plant growths on his land in any way he chooses seems to me nearly inalienable, though of course, there are necessary restrictions even in this connection regarding weeds and poisonous plants.

Can there be any reasonable objection on the part of the florist trade to the establishment of full protection on public lands against commercial collection, also excessive scientific collection?

If the commercial raising of certain uncommon wild plants is too difficult to be economic and feasible will not the florist trade be willing to refrain from the use of such species, even though scattered areas may still have considerable supplies available?

*Resident Investigator, Brooklyn Botanic Garden.

CAPE COD WARS ON SIGNBOARDS

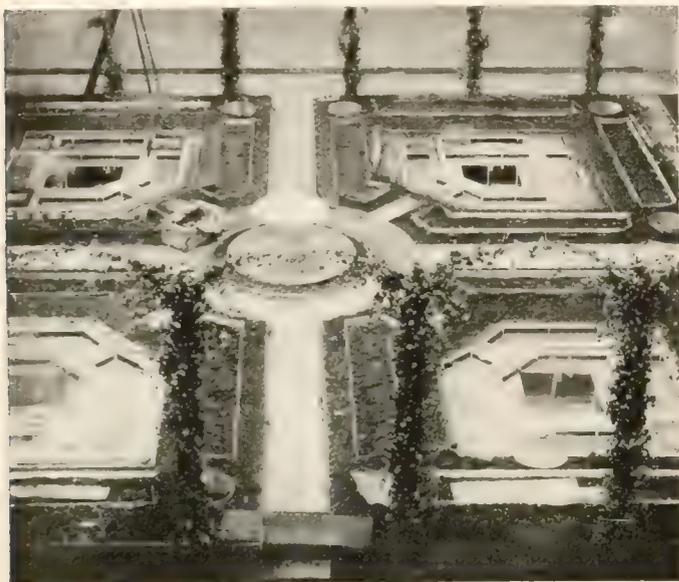

CERTAIN important groups of Cape Cod residents have begun a campaign against the advertising signboard. Their first aggressive move was in the form of a petition to the Board of Public Works signed by the Selectmen of fifteen towns in Barnstable county, representing among other things that Cape Cod people are largely dependent for their prosperity on Summer visitors. Whatever mars the distinctive scenic characteristics of the Cape tends to lessen its attraction for these temporary sojourners. Advertising signboards, it is contended, have this effect.

That, in brief, is the ground on which the Cape Cod folk pray that certain Cape highways be declared "scenic

highways" and that as such they be relieved of the sign boards.

During the last week in April those interested in the maintenance of the billboard system of rural advertising made answer through counsel to the complaints set forth in the petition. In substance their reply was a general denial of pretty much everything the complainants alleged. It denied that the appeal itself was made in good faith; denied that hotel owners were in sympathy with it; characterized as "impractical persons" artists who object to signboards and declared that the women's clubs supporting the anti-billboard movement are doing so without careful study of the subject.

The battle in which Cape Cod residents are now engaging has been fought to a finish in several localities. In 1902, under the leadership of Franklin Murphy, then Governor of the State, New Jersey conducted a spirited

The under structure of the tulip garden at the International Flower Show

and very aggressive campaign against billboard advertising. It was not successful. An obstacle then encountered, and one which the Cape Cod movement may encounter, proved to be insurmountable. This was the willingness of landowners to rent ground for the erection of signboards and to let the sides and roofs of barns and sheds for advertising purposes. There was no way to prevent this from being done unless a public nuisance was created. That advertising signboards were a public nuisance could not be proved to the satisfaction of the courts.

In the final outcome dependence must be placed on appeal to public spirit over private interest.—*N. Y. Herald.*

Several years ago when the National Association of Gardeners undertook to inaugurate a propaganda to make Sign Board advertising unpopular and sought the co-operation of other organizations in its endeavor, the response was most encouraging and considerable publicity was given to the movement both through the press and otherwise, but in time interest waned. The association has maintained from the beginning that all efforts to control the signboards along the highways through legislation would only result in much wasted energy. It was estimated that \$40,000,000 was spent on signboard advertising in 1920. The signboard interests are well organized and strongly entrenched with an array of legal talent and lobbyist to combat any adverse legislation

which may arise against them, while their opponents lack organization. One suggestion made is that a heavy tax be placed on signboards. This, however, would not disturb the successful advertisers for it would only mean a slight increase in the cost of their signboard advertising. Another suggestion was to have the "anti's" pledge themselves to make the products advertised on signboards unpopular—in other words, boycott the goods so advertised. But who can imagine a woman, or a man either, on seeing a bargain offered and becoming interested, recalling that the advertiser's signboards at some time offended them by obstructing the scenic beauty along the countryside.

What has so far been done to make the signboards unpopular seems to have resulted only in making them more popular in the eyes of the advertisers. It is true that through moral suasion, an advertiser is occasionally prevailed upon to remove an objectionable signboard from a residential section or along a parkway, but this may be compared to picking an aphid from a rose bush and believing that thereby the entire pest will be destroyed. What is necessary is an effective contact remedy to reach all the signboard advertisers. Who can supply the formula?—EDITOR.

CONSTRUCTING A FLOWER SHOW GARDEN

(Continued from page 145)

twenty-six hundred Darwin tulips, fifteen hundred potted pansies, seventy-five hundred *buxus Suffruticosa* (from South Carolina), seven hundred and fifty plots of grass

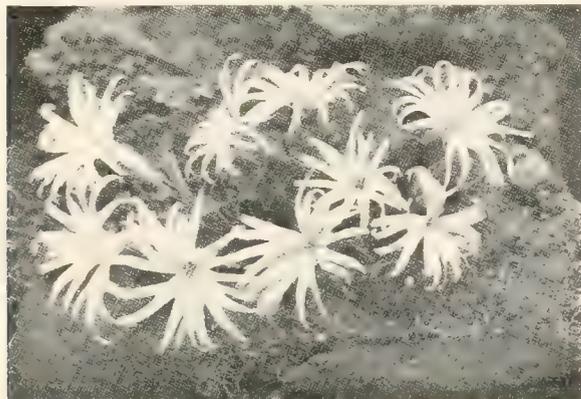

A section of the tulip garden as it appeared when planted

and one hundred and fifty pressed bales of Holland peat. There was also a large quantity of English ivy, some dogwoods, and standard cherry trees, besides other seasonable flowering shrubs. Twenty-six tall cedars, all in tubs, served as a background. The quantity of planting material employed gives an idea of the immensity of the undertaking in creating a garden on an exhibition floor. There is no question but that such exhibits aid American horticulture in the development of better gardens.

When you know a thing, to hold that you know it; and when you do not know a thing, to allow that you do not know it; this is knowledge.—*Confucius.*

Foreign Exchange Department

SILENE HOOKERI.—Although introduced from California nearly half a century ago, this truly marvelous little plant, with its two-inch wide blossoms of clearest rose pink, rayed white, is still a rare plant in our rock-gardens. *Silene Hookeri* is readily raised from seed, and the young plants proceed at once to make a long thong of a taproot, crowned with a tuft of longish, narrow leaves of soft texture and grey with down. These leaves flop about loosely on the ground, and are safest on a layer of shingle to keep them clean and able to fulfil their natural functions. If raised in gentle heat early in the year, the young plants begin to flower in their first Summer. They send up from between the leaves about two-inch long stems, which flop about in various directions, each one crowned with one enormous, deeply-fringed

Silene Hookeri (Courtesy of Gardening Illustrated)

flower. This display continues for many weeks in well-established specimens, and good seed is produced fairly freely. In the Winter the plant dies down, out of harm's way, and provided the drainage is really perfect it appears stronger than ever next Spring. The plant is so beautiful that a little trouble is well repaid, and people who object to a little extra fuss must give up all thoughts of succeeding permanently with this plant in the open garden. There is, of course, not the slightest difficulty in growing it in pots or pans in sandy loam and leaf-mould for the Alpine house. In the open choose a place at the foot of a south-facing cliff or boulder—if on a sharpish slope so much the better. Dig out the soil for fully eighteen inches, give six inches of brickbats and broken

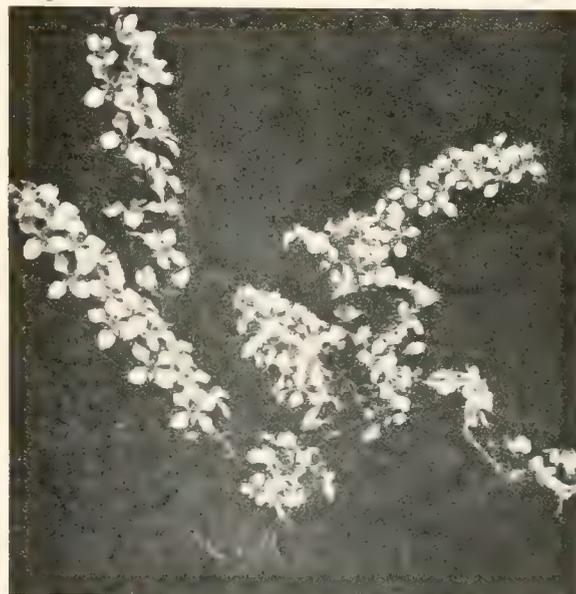

The remarkable herbaceous plant *Pachysandra Procumbens* (Courtesy of the Garden)

crocks for drainage, and fill in with a sharp screen mixture; four parts of limestone or granite chips to one part of leaf-mould and loam mixed, and plant as close up to the cliff or boulder as you can, and if your garden is in a district with a fairly pure atmosphere *Silene Hookeri* will probably settle down with you contentedly, and give you an increasing number of flowers from year to year. *Gardening Illustrated*.

PACHYSANDRA PROCUMBENS.—This is quite an interesting herbaceous plant, which has the additional merits of being beautiful and uncommon. Its attractiveness lies chiefly in the thickened stamens from which it derives its generic name. The

sweet-scented flowers are monoecious on the same spike; the staminate flowers, which are in the majority, being above, while the few pistillate blossoms are below. All are without petals, the staminate flowers consisting of four greenish purple sepals, four stamens, which are opposite the sepals, and long thick filaments from one-third to half an inch long, which are exerted; while the few pistillate flowers, the sepals of which are variable, have a three-celled pistil, with two ovules in each cell and three comparatively large fleshy styles, which are spreading. The plant is of spreading habit, with stout, unbranched stems about nine inches in length, bearing at the top a cluster of dark bronzy evergreen leaves from two inches to four inches long, ovate or obovate, obtuse or acute at the apex, the upper part coarsely dentate, the lower part entire, narrowing at the base into a petiole, either equal to or shorter than the blade. The foliage gives the appearance of a ring surrounding the dense cylindrical spikes of flowers, which rise from the axils of the scales from the lower part of the branches. The culture of the plant is quite simple; it grows in ordinary soil and is a suitable plant for woodland or a semi-shady position. It can be propagated from cuttings, but the most convenient method is by division. It is a native of the South-Eastern United States and known as the Allegheny Mountain Spurge, but it is also found in Carolina and Kentucky. Other species of this interesting genus suitable for similar positions are *P. axillaris*, a Chinese species, and *P. terminalis* from Japan, as well as a variegated-leaved variety of the latter, sometimes grown in greenhouses as a foliage plant, although it appears to be perfectly hardy.—*The Garden*.

FENDLERA RUPICOLA.—*Fendlera Rupicola* is a beautiful deciduous shrub that deserves to be better known, for few plants are more effective, and at the same time more easily grown if

Fendlera Rupicola (Courtesy of Gardeners' Chronicle, British)

given a sunny, warm position. This interesting member of Saxifragaceæ is closely allied to *Philadelphus*, but differs from that genus by reason of its eight stamens and superior ovary. The beautiful white or faintly rose-tinged flowers, which individually somewhat resemble a Maltese cross, are from one to one and a half inches across and usually borne solitarily, but sometimes in threes on short twigs on the previous year's growth; the petals are rhombic-ovate and contracted at the base into a distinct claw, while the cluster of bright yellow stamens stands up erect on petaloid filaments and adds to the beauty of the flower. The almost sessile leaves are rigidly coriaceous, lanceolate on the sterile branches, about one inch long and one-half inch wide, prominently three-nerved, revolute at the margin, with short, stiff bristles above the greyish tomentum beneath, while the leaves on the flowering shoots are much smaller, being linear and clustered on short twigs. This sturdy, rigidly-branched, deciduous shrub is a native of the South-Western United States, and is found growing on the sun-burnt slopes in Texas, New Mexico, Arizona and Utah. It is considered to be one of the most beautiful plants of its own region, where its profusion of white, or rose-colored flowers is said to give it the appearance of a small Peach tree. The illustration shows a spray from a fine specimen eight feet high, growing against the Cactus House in the Botanic Garden, Cambridge. It is not particular as to soil and is readily raised from seed, or from cuttings of rather soft wood placed in gentle heat.—*Gardeners' Chronicle* (British).

IN PRAISE OF THE GAILLARDIA.—One often wonders why many gardeners do not make more use of this pleasing and accommodating perennial. There are so many points in its favor that it should receive more attention than is usually given to it. Still it is a very uncomplaining plant even though it does not always receive the due reward of its merits.

What are its merits? I have been trying to think of one word in which they could be summed up succinctly but the task is beyond me.

It is a good drought resister and produces in abundance, gaily colored flowers which enliven many a dull patch in the garden. The flowers are excellent for table decoration, lasting well in water and lending themselves naturally to artistic arrangement, so that the veriest tyro in the art of arranging flowers can make them look pleasing.

It is not exacting in the matter of soil or attention, yet if it does not get very much, it murmurs not nor complains but goes on producing its bright and glowing flowers in abundance.

Surely the Gaillardia is worthy of a little more attention and consideration than it usually receives at the hands of most gardeners. Grown in masses it is very beautiful and every garden should, if there is the slightest possible chance, have at least one far-sized bed given up to it.

According to the dependable Johnson, the Gaillardia hails from N. America. Those who prefer a good old-fashioned name will be glad to know that the Gaillardia rejoices in two—the Blanket Flower and the Flannel Flower. Of the two the former seems preferable and is certainly suggestive.—*So. African Gardening and Country Life*.

AN EARLY-FLOWERING ROCK PLANT.—The Scrophulariad, *Synthyris reniformis*, is a native of North-West America. The tubular blooms are about a quarter of an inch in length, pale violet in color, and they are produced in quantity on erect spikes six inches or more in length. The leaves also are attractive, being deeply toothed at the margins. This plant is quite hardy and in its native habitat it is found growing in moist places, so it should be given a damp spot in the rock garden; although I have grown it successfully in various positions, except where it is heavily shaded. A cool loamy soil is needed, and in a dry season it may require water at the root to keep it going until more moist conditions prevail. This year it has flowered freely, and the earliness of *S. reniformis* should warrant it a place in every rock garden, while for an alpine house it would be found most useful for an early display. The plant can be increased by division and from seeds.—*The Garden*.

VIOLET CRESS (*IONOPSISIDIUM ACAULE*).—It would scarcely be thought that so diminutive a plant could possess much attraction in the flower garden—as it grows but three inches high—yet this is so, the tiny little plants covered with their lilac blue flowers being much admired at the present time, December 6th. The flowers vary considerably, both in size and color, and so freely are they borne that every plant becomes a cushion of bloom. Like all the Cresses, it appears to love cool, moist conditions. Its life is short, but the self-sown seeds germinate so quickly that plants are in flower more or less throughout the year. In the present instance it is used to carpet the ground among seedling Carnations, for being so small it does not in any way interfere with the latter. Where one wishes to make such beds attractive during the Winter a few seeds should be scattered among the plants in September or early October.—*Gardening Illustrated*.

PRIMULAS.—Where successional batches of the *sinensis* type are required, seed may now be sown, followed later on by other sowings, according to requirements. For decorative purposes the stellata varieties are most suitable, not only for their light, elegant effect, but also for their length and freedom of flowering. The variety Coral Pink and the "blue" varieties make a very effective color combination, as also do the red and white varieties. The seed should be sown in a light, rich compost, and may be germinated in slight warmth. Germination is generally very irregular, thus the seed pots should not be discarded too soon. During the Summer months the young plants should be grown in low pits or cold frames. The plants should be watered carefully at all times and kept shaded during the hottest part of the day. They enjoy a light, rich compost to which some old mortar rubble should be added. By growing them on a second year very fine specimens can be obtained, and for this purpose plants should be selected from a sowing made rather late last year. A bench of stellata varieties grown in this way has been in flower for close on six months in the conservatory at Kew, and at the time of writing are still a mass of flowers.—*Gardeners' Chronicle* (British).

IRIS LACUSTRIS.—One of the smallest of Irises, but an exceptionally charming one, is the miniature *Iris lacustris*, a perfect gem, smaller in all its parts than the equally charming *I. cristata*. It comes from the gravelly margins of some of the North American lakes, such as Lake Huron, and loves a moist soil, which, however, should not be too stiff, but rather friable and gritty.

There it will thrive and spread with fair rapidity, always provided its arch enemy, the slug, does not crop it to the ground. It grows only about three inches high, and gives its pretty leaves, like miniatures of those of the Flag Irises and exquisite little flowers, of a lovely amethyst-blue with a golden crest. It is a lovely little Iris, which may be planted in Spring to bloom the same Summer.—*Gardening Illustrated*.

PLACING FLOWER BEDS.—Many flower beds that in themselves are pretty are nevertheless ineffective because they are poorly placed. In the middle of the lawn a flower bed looks isolated and therefore is not pleasing, although an observer may not know just why the bed fails to satisfy the artistic sense. A flower bed should relate itself to the rest of the garden, for it is not there for its own sake but only as a part of the general scheme. When it has a hedge, a mass of shrubbery or a vine-covered fence for a background, the eye is gratified, for it finds exactly what it unconsciously seeks, a screen against which to view the flowers.—*Canadian Florist*.

THE TREE IVIES.—Everyone is familiar with the climbing forms of Ivy upon walls and buildings, but what is known as the Tree Ivy is not so well known. These Ivies are, in reality, merely a modification of the commoner form, and are principally valued on account of the fact that they are of a shrubby nature, and that they produce berries at an early stage of their existence. They are of comparatively slow growth, but they are useful in the garden scheme in various ways. When planted in masses their evergreen character makes them attractive throughout the year; they may be used in the foreground of shrubberies, and they are not unpleasing in colonies and on a lawn. As pot plants, too, the Tree Ivies are serviceable to those who have no other glass than an unheated greenhouse, and who must work only with quite hardy plants. Such plants are very useful for placing on balconies or in porches, the green foliage and, in their season, the berries, being noteworthy. There are several distinct kinds of Tree Ivies, among them *Hedera Helix arborea*—the commonest variety—*H. fructu luteo*, with yellow berries; *H. argentea marginata*, with silvery variegation; and *H. aurea*, the foliage of which is, more or less, suffused with yellow.—*Gardening*.

THE LEGEND OF THE XMAS ROSE

When the three Kings did come to Bethlehem
To greet the Babe, new-born, to heal our woes,
A little shepherd girl did follow them,
Hight Madelon. But for that she was poor,
And had no present to the Babe to bring
She lingered sadly all outside the door
In tears, and prayers, and humble sorrowing.
To whom came Angel Gabriel, and did say,
"What is your sorrow, little Madelon,
Why weep you so, and why thus lonely pray,
When all the world from Satan's thrall is won?"
Quoth she, "I have no present for the King
Who has no flower. Ah, woe is me,
For it is cold, and lacks so long to Spring,
Had I but roses now, all fair to see."
Then with his rod he struck the frozen ground,
Where out fresh roses there did straight appear,
These gathered she, and in a posy bound
Did bring to Jesus Babe, withouten fear.

* * * * *

"In old Monks calendar the Xmas rose is allotted to St. Agnes as patroness of Purity. Therefore it was much used by the Ancients to purify their Temples and homes."—*So. African Gardening and Country Life*.

RHODORA CANADENSIS.—This is such an easily grown, charming little shrub that one wonders why it is not more often seen. It is adaptable for the rock garden (being no more than two feet to four feet in height), the front of the border or open woodland, and all it asks is any cool loam that does not dry out too quickly in Summer. Peat and leaf-mould it enjoys, but these are not always essential. We have grown *R. canadensis* for many years and not once has it failed to produce a mass of blossom in early Spring. It generally flowers just as *Rhododendron præcox*, *R. ciliatum*, and other early kinds are going off and, being deciduous, the leaves do not appear until the blossoming is over. The flowers, which are borne in clusters at the tips of the twigs, are a vivid rose-purple with long, silvery stamens which protrude with an upward tilt like those of a Honeysuckle. Another name for *Rhodora canadensis* is *Rhododendron canadensis*.—*Gardeners' Chronicle* (British).

ROOT CUTTINGS.—Root cuttings are useful for increasing stock of many plants that are difficult to propagate in any other way. Plants producing suckers are easily worked by this method. Many plants that never sucker naturally will send out shoots when

root cuttings are inserted in sand. Autumn is the best season for making root cuttings as the ripened root contains a large amount of matter stored up, which will produce either roots or shoots. Some plants require heat to strike their root cuttings, but there are many others which will grow easily without any heat. A good subject to try root cuttings of is the Californian Poppy, *Romneya coulteri*—*See African Gardening and Country Life*.

Brief Horticultural Jottings

Under the heading "A Spring Garden Growing Wild in the Fields of Texas," the *Christian Science Monitor* writes: The botanical name for the Texas bluebonnet, is *lupinus texensis*. Old settlers have named this plant Buffalo Clover. This is the state flower, and covers the meadows, hillsides, railroad right-of-ways, and roadsides with its extravagant blossoms and foliage from April until July. The plants stand about ten inches high, and have palmately compound leaves and elongated clusters of ultramarine with purple-colored flowers. Each flower is a bonnet-shaped series of petals, with a white blotch on the upper petal, next the bonnet crown, which turns to pink as the flower grows older. After being open about six days the blossom is dropped and a pod appears. These erect, full, silky, hairy pods form up the flower stalk as the blossoms continue to open nearer the end. The flowers cluster thickly on a pencil-size stalk which is usually six inches long and resembles the well-known wisteria blossoms in arrangement. One plant often yields eight clusters. Bluebonnets grow in patches on hillsides or stream banks where the foundation is rocky and the soil is well drained. The roots of these plants are interesting because of the nodules that form to gather the nitrogen from the soil.

That Madison, N. J., is the location of one of the two largest sassafras trees in the world was recently brought to light in an editorial in the *New York Tribune* which stated: It has been declared by United States government experts to be one of the largest sassafras trees ever known in the world, the other, of almost precisely the same gigantic proportions, being in Missouri. Such a unique wonder of the sylvan world may well be the object of civic pride and guardianship. A community which is so fortunate as to be endowed by Nature with a living memorial of colossal stature, vital and vigorous with the strength of centuries, should surely conserve it at least as jealously as it would any structure of men's hands.

The trunk on the big sassafras measures about eight feet in diameter, and one of its enormous branches extends over the road. It is believed that its age is more than 150 years, with 200 years being more than nearly the exact figure.

In an article in the "Horticulture in Holland," Quarantine No. 37 and the Federal Horticultural Board are again being severely condemned. It asserts that European countries will take reprisals, first against California fruit which is being imported in enormous quantities. Diseases, it is claimed, have been found on this fruit which form a great danger to European Nurseries and if Europe should adopt American measures, American fruit must be prohibited from Europe, and the same fruit which is now obtained from California can be imported from South Africa and Australia. The statement is made that leading men in some countries have already come in contact in order to bring their governments to this point of view: if America goes on to exclude European horticultural products, it will only be right to exclude American fruit and agricultural products from Europe. This will in the coming years be the slogan for the International Congresses and those interested will not rest until the slogan is put into practice.

Called according to its alias, the "boll weevil," this bug which has carried destruction to southern planters' fields has had bestowed upon it a distinction never before vouchsafed to any insect of any species: a real monument has been erected to it by the town of Enterprise, in Coffee County, Alabama, with a real inscription

In Profound Appreciation
Of the Boll Weevil
And What It Has Done
As the Herald of Prosperity
This Monument Is Erected

When locusts lit on Egypt they did hardly more damage, some Alabamans assert, than did "boll weevil" when it chewed up Coffee County's cotton crop, the second season. Production fell from 35,000 bales to about 10,000. Coffee County, facing the need of innovation or bankruptcy, turned to raising corn, sugar-cane, cattle, hogs, peanuts, hay and sweet potatoes with a will. The result was

that peanuts alone returned \$5,000,000, it is said, in a season, which is not considered bad for a county of 1,500 farmers.

The boll weevil's ravages turned crop rotation from theory into a necessity in the South. The monument is more than a town's passing whim, it marks the time when the cost of efficient production was discovered, on which discovery the cornerstone of agricultural success has been laid.

An international conference of phytopathologists and entomologists will be held at Wageningen, the center of one of Holland's market gardening districts, from June 25 to June 30. The conference will be presided over by the Dutch Premier and the Minister of Agriculture, and the honorary Presidents include Dr. L. O. Howard, Director of Entomology of the Washington Department of Agriculture.

One of the chief questions under discussion will be the carrying of plant sickness and insect plagues, and international co-operation and control in preventing the transporting of these plagues.

Great interest has been evinced in the conference from all sides, and no less than twenty-one foreign countries, including the United States, are sending fifty-three experts as delegates.

Dr. Howard will deliver one of the first lectures on International Co-operation to Combat Plant Sickness and Insect Plagues." Dr. C. L. Shear of the United States will lecture on "International Statistics and Supervision of Plant Sickness."—*New York Herald*.

It is reported from Germany that an experimenter has obtained good results by storing juicy fruit, such as pears, in peat dust, says *The Fruit-Grower* (London). By reducing evaporation, peat dust is said to enable the fruit to ripen without wrinkling. When damp and loosely packed peat dust is used, fruit will keep good, and, so the report says, even improve in color. It is not claimed, however, that the use of peat dust will arrest or eliminate decay if the fruit is in any way infected by bacteria before storage.

Comments from Our Readers

Your article in the May number, "Planting Trees as Memorials," should not only inspire "tree lovers" to advocate the use of trees for memorials, but should urge them to greater effort to spare those silent sentinels that have stood, for many, many years, and which are often thoughtlessly sacrificed for "civic improvements" where a little consideration would not only save them but would also benefit the contemplated improvements. It is not uncommon to see beautiful specimens destroyed to make a contractor's job easier, where with a little extra exertion, the work could be accomplished without molesting the trees. It takes but the blow of an ax to destroy what it has taken Nature a century to produce, and it is not in man's power to replace it. The great value of trees to a community is not recognized as it should be. If it were, there would be less ruthless destruction of them.

Chestnut Hill, Pa.

Mrs. H. T. H.

In reading the reprints and excerpts in the *GARDENERS' CHRONICLE* from the foreign gardening magazines, it is really surprising how much better some of the European gardeners are informed on our native plants than we appear to be here at home. One hears so much of being deprived of European plants through Quarantine No. 37, that he feels we possess nothing worth while of our own, while the foreigners write enthusiastically over their experiences with American species. Instead of bemoaning their fate over the loss of foreign supply, why do not the American nurserymen exert themselves to develop those beautiful American shrubs that we read of, but do not seem to be able to obtain?

New Rochelle, N. Y.

Mrs. F. B. L.

In your current issue, you ask readers to suggest what may occur to them. Repeatedly in your paper—and naturally elsewhere as well, I read of varieties that I cannot find listed in any catalog. Last year this occurred in several articles on rare plants and alpines. In this very issue, you have two articles on Spring flowering bulbs, and at least half of these I cannot locate. Whereas I realize it is contrary to the policy of most papers to introduce in reading matter anything that might appear to be of an advertising nature, still I do not believe you would antagonize any dealer if you would in some way, note where the plants or seeds were obtainable. It would, I am sure, be of great value to readers.

Greenwich, Conn.

H. J. E.

H. J. E.'s suggestion is an excellent one, and the *GARDENERS' CHRONICLE* will adopt it at an early date, when rare varieties of plants or bulbs are referred to by stating, whenever possible, where they may be obtained.—Editor.

National Association Of Gardeners

Secretary's Office, 286 Fifth Ave., New York

1923 Convention, Pittsburgh, Pa., August 14, 15, 16, 17.

The aims of the association are to elevate the profession of gardening by improving conditions within it.—To cement a closer bondship among all engaged in, and interested in, gardening—to create a greater confidence between employer and employee.

Co-operating with the Massachusetts Agricultural College, the association conducts a course in training young men for the profession, whereby they obtain theoretical knowledge as well as practical experience.

OFFICERS 1923

President JOHN BARNET, <i>Sewickley, Pa.</i>	Vice-President WILLIAM GRAY, <i>Newport, R. I.</i>
Secretary M. C. EBEL, <i>New York, N. Y.</i>	Treasurer MONTAGUE FREE, <i>Brooklyn, N. Y.</i>

TRUSTEES (For 1923)—Thomas W. Head, D. L. Mackintosh, Arthur Smith, New Jersey; Robert Cameron, Massachusetts; Andrew L. Dorward, Rhode Island.

DIRECTORS—(To serve until 1924) William Hertrick, California; George H. Pring, Missouri; Robert Weeks, Ohio; Thomas Wilson, New York; Harold Bryant, Connecticut; Harry Cartwright, Michigan; H. Ernest Downer, New York. (To serve until 1925) George Wilson, Illinois; James Stuart, New York; William Kleinheinz, Pennsylvania; Edwin Jenkins, Massachusetts; Carl N. Fohn, Colorado; Joseph Tansey, New York; John Tonkin, Pennsylvania. (To serve until 1926) Alexander Michie, New York; George F. Stewart, Massachusetts; Theodore Wirth, Minnesota; George W. Hess, District of Columbia; R. P. Brydon, Ohio; William C. Rust, Massachusetts; Charles Schrafl, Wisconsin.

CLEVELAND, O.: R. P. Brydon, chairman; Arthur Brown, Cleveland, secretary.

THE COMING PITTSBURGH CONVENTION

The time is drawing near for the annual convention at Pittsburgh on August 14, 15, 16, 17. It is but two months off so it is none too soon for members to make their plans to absent themselves from work for a few days to actively participate in the affairs of the association and to engage in the discussions of the subjects which will be brought up concerning the welfare of the gardener and his profession. There will not be an idle moment, for when the visiting members are not at work, they will be kept busy with the entertainment that is being planned for them.

The Ladies' committee is not overlooking the interest of the wives and daughters of the gardeners who are expected to attend.

President Barnet and his associates on the various committees are looking forward to greet a big gathering. So let us not disappoint them. Remember that "All work and no play makes Jack a dull boy."

THE CONCLUSION OF AN UNPLEASANT INCIDENT

The many communications which have been received from branches of the National Association of Gardeners, local societies, and individuals, show that the resentment among the gardeners towards the *Florists' Exchange* over its unfriendly attitude towards the gardeners and its unwillingness to publish the gardeners' side of the controversy was far reaching. Space will not permit publishing each report received in detail, but the resolutions from numerous organizations were unanimous in their approval of the stand taken by the association in defense of the gardeners.

At the May meeting of the Gardeners' and Florists' Club of Boston, Mr. Thommen who made the accusation that disturbed the heretofore friendly relations between the gardeners and the *Florists' Exchange*, refused to substantiate his statement and was given the alternative of retracting, apologizing, or resigning from membership in the club. He preferred the latter course and the club at once unanimously accepted his resignation. I believe that I truly voice the sentiment of the members of the N. A. G. in saying that they also cherish the hope expressed by the *Florists' Exchange* in its last editorial "that time will soon see the closing of the breach under the healing influence of a new mutual understanding and a sympathetic co-operation looking to that consumation to which we are all dedicated—the future welfare of horticulture."

The ancient and honorable profession of gardening has passed through this regrettable affair unscathed. The gardeners will continue to strive for the advancement of their profession and to improve the condition within it, so that the gardeners of the coming generations will find the profession a more lucrative vocation than do the average gardeners of the present age, who must accept as part compensation for their work, the enjoyment they find in toiling with Nature to produce that which comes out of the soil and without which man cannot long survive.

M. C. E.

WESTERN PENNSYLVANIA BRANCH

A meeting of the members of the Western Pennsylvania Branch of the National Association of Gardeners was held in the Carnegie Library, Pittsburgh on May 15th, Manus Curran, Chairman, presiding.

A letter was read from the Allegheny County Conservation Federation inviting this branch to become a member of their organization. The Secretary was instructed to write to the Federation advising it that the Western Pennsylvania Branch heartily endorses its objects, but inasmuch as most of the members are members of the Sewickley Horticultural Society or the Pittsburgh Florist's Club, it does not feel it is necessary to hold membership in the Federation.

The chairmen of the various convention committees all reported progress, and everyone is co-operating to make the national convention at the Fort Pitt Hotel, Pittsburgh, August 14, 15, 16 and 17 a success.

The application of Robert Gardener for membership in the National Association of Gardeners was endorsed by this branch.

Three members joined the branch at this meeting making a total of 31 paid up members to date.

HENRY GOODBAND, Secy.

NASSAU CO., L. I. BRANCH

At the last meeting of the Nassau Co., L. I. branch, held at Winthrop Hall, Westbury, L. I., Chairman Duthie announced the resignation of John Forbes as treasurer as he had moved from the district. John McIntosh was appointed to fill the vacancy. On the proposal of a member, it was voted that it was the feeling of the meeting that the GARDENERS' CHRONICLE should be owned and operated by the association. The secretary was instructed to write the various branches to obtain their views on the subject. (This has already been carefully discussed by the Executive Board of the association in the past and it was the unanimous opinion that it would be both impractical and impossible for the association to conduct its own official organ, if for no other reason than that its financial resources would not yet permit it; M. C. E.) After further animated discussions, it was announced that the next meeting of the branch would be held at the Parish Hall, Oyster Bay, at 8 o'clock sharp on June 27. Members please take note of this date as it will be the only notice given. Govern yourselves accordingly.

JOHN R. McCULLOUGH, Sec.

COMING BRANCH MEETINGS

The Cleveland branch will meet at 7 o'clock on June 18 at the Alhambra Restaurant, Cleveland.

The Boston branch is to hold a meeting early in August to give members an opportunity to submit and discuss suggestions to be presented at the annual convention.

PRESIDENT JOHN BARNET

John Barnet, president of the National Association of Gardeners, was born near Grieff, Perthshire, Scotland, forty years ago. From there his family moved to Dougalston, Milngavie, near Glasgow, the residence of T. R. Ker, Esq. where his father is now Head Forester. Mr. Barnet began his gardening career at the age of twelve years, and at fifteen years of age was a full fledged apprentice. He acquired a thorough training on some of the most famous estates of Scotland. (Mr. Barnet states that in those days competition was very keen and one almost required a letter from a minister to get a job.) After satisfying himself that he had acquired about all the experience he could gain, he decided to try the U. S. A. After he had engaged in several positions in Massachusetts, and worked under the guidance of William N. Craig at Faulkner Farms, Mass., the latter recommended him to Mrs. J. D. Lyon of Sewickley, Pa., in September, 1915, for the

John Barnet

superintendent of her estate, which position he now occupies. Mr. Barnet has always taken a live interest in the horticultural activities in and about Pittsburgh, and is a past president of the Pittsburgh Gardeners' and Florists' Club. He is one of the organizers and first full term president of the Sewickley Horticultural Society. Mr. Barnet is a life member of the National Association of Gardeners and of the Royal Caledonia Horticultural Society, a member of of the Society of American Florists, and of the American Dahlia, Rose, Sweet Pea, and Chrysanthemum Societies. While he has the reputation of being a thorough gardener and a capable grower, his active affiliation with many organizations has also endowed him with the qualifications of an excellent parliamentarian.

James Barnet, superintendent of the Asa G. Candler, Jr. estate at Atlanta, Ga. and Lewis Barnet, superintendent of the R. B. Mellon estate, Pittsburgh, Pa., are brothers of our most worthy president.

VICE-PRESIDENT ROBERT P. BRYDON

Robert P. Brydon, Vice-president of the National Association of Gardeners was born in Yarmouthport, Mass., thirty-seven years ago. His father, James Brydon, was gardener to Congressman Simpkins, and later and up to the time of his death, gardener to Mrs. Bayard Thayer at Lancaster, Mass. He was known as an unusually able gardener, and skilled as a grower of exhibition chrysanthemums and water lilies. Robert P. received his training in this country. After a course at the Massachusetts Agricultural College, he was over four years with the Reading Nurseries, Reading, Mass. and then for two and a half years with Edward W. Breed at Clinton, Mass. From there he went to the estate of

Cyrus McCormick at Lake Forest, Ill.; thence to "Glennallen," the estate of Mrs. Francis P. Prentiss, Cleveland Heights, Ohio, where he has been located for the past ten years, first as gardener and then as superintendent which position he now holds.

Mr. Brydon is always prominently associated with the horticultural events in Cleveland, as an active and enthusiastic worker. He is a member of the Cleveland Florists' Club, and of the Cleveland Horticultural Society of which he has thrice been president, and twice treasurer. At the present time, Mr. Brydon is chairman of the Flower Show Committee, always taking a keen interest in Cleveland flower shows.

DOES THE LABOR BOOM BENEFIT THE GARDENER?

With ordinary garden laborers demanding sixty cents an hour and ten hours to the day, many owners of country homes and suburban home gardens have decided that the regular employment of a trained gardener will prove more satisfactory and less costly, while relieving them of the responsibility of personally supervising the work of a garden helper. And so there has been more than the usual demand this season for the experienced gardener on small places.

While some garden owners at first demurred over the pay asked by competent men, when the gardener's side was presented to them, they usually were ready to accept his viewpoint. Others on being asked what salary they would pay, would promptly reply, "Whatever is customary," or "Whatever such a man deserves." Reports that have been received show that the garden owners who are for the first time employing practical gardeners, are quite satisfied with their new experience.

There appear to be some garden owners, however, who have yet to learn that a competent gardener should not be engaged

Robert P. Brydon

as a handy man may be, for the employer should interest himself in first thoroughly investigating the applicant's past experience. And likewise a thorough gardener desires to see the place before he engages for it, so that he may satisfy himself that he possesses the qualifications to accept the position.

There are agencies to which one may phone and state, "I want a gardener, sixty dollars and board. Send one to the place tomorrow." And so the next morning the "gardener" arrives, luggage, and all, prepared for work, but it is found that while he may know something about geese and pigs and some vegetable crops, he possesses absolutely no knowledge of what he was supposed to be engaged for—gardening—and these are the circumstances which cause garden owners to complain that they have such terrible experience in employing gardeners. Their trouble is caused by seeking gardeners in the wrong places.

LOCAL SOCIETIES

WESTCHESTER AND FAIRFIELD HORT. SOCIETY

The regular monthly meeting was held in Greenwich Y. M. C. A., May 8th. Two new members were elected.

An invitation was received from the American Iris Society to attend its annual meeting and flower show to be held in New Rochelle, June 1 and 2. Following the business session the society with members of the Rye, Riverside and Greenwich garden clubs as its guests, gathered in the auditorium to hear Loring Underwood, a noted lecturer and botanist, speak on "Old New England Gardens." In his discourse he mentioned the Wayside Inn, Salem, Mass., the John Quincy Adams estate, and many others. He showed pictures beautifully colored of these places and their gardens. His talk was thoroughly enjoyed by all present. The audience agreed it was one of the most unique and interesting lectures they have heard.

For the monthly flower exhibit, first prize went to Edwin Beckett for a *Laelia Fascinator*; second to James Stuart for a *Calceolaria*; third to William Smith for a *C. Mossiae*. Other exhibits included two vases of roses, *Columbia* and *Ophelia*, W. D. Robertson; three vases of *Spiraea*, John Wilson; *Antirrhinums* from George Hewitt, William Sealey and John Kearnes; tulips from John Andrews. John Wilson received first, and John Andrews second, for vegetables.—ANDREW KNEUKER, Cor. Secy.

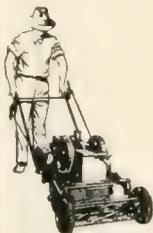

IDEAL Power Mowers do more than merely cut the grass. In the same operation they trim borders closely, roll the lawn to velvety smoothness and greatly retard the ravages of worms and other lawn pests. All this is done at a small fraction of the cost when done by hand.

An ordinary laborer can be trusted with the simple, sturdy Ideal mechanism. He will do the work of from three to five men with hand mowers and rollers.

Interesting information on lawn care will be sent upon request.

Ideal Power Lawn Mower Company

R. E. Oels, Chairman
 131 Kalamazoo Street, Lansing, Michigan
 New York, 13-19 Hudson St. Chicago, 11 E. Harrison St
 Dealers in all principal Cities.

Ideal Junior cuts a swath 22 inches wide. Capacity from 3 to 4 acres a day

Ideal 30" mower cuts a 30 inch swath and mows from 6 to 7 acres a day

IDEAL Power Lawn Mowers

NASSAU COUNTY HORT. SOCIETY

The regular meeting was held on May 10 in Pembroke Hall, Glen Cove, L. I. President James Gladstone occupied the chair. E. Tubbs and Charles Carter were elected to active membership. The monthly exhibits were judged by James Holloway, Ernest Westlake and William McCloud, whose decisions were as follows: 12 Red Darwin tulips, first, John F. Johnston; 12 Darwins, any other color, first, Frank D. Johnson; a very fine vase of dahlias, grown inside and exhibited by J. W. Everett, was awarded a Cultural Certificate; vase of *Polemonium reptans*, exhibited by Edward Harris, honorable mention. The Summer Show schedule was read and the show will be held on June 14 in Pembroke Hall. H. C. Van Ginover exhibited some fine narcissus in a talk on bulbs affected by the ruling of the Federal Board. Exhibits for June 13 will be 12 mixed H. P. roses; 12 mixed T. roses; 9 spikes of campanula. ARTHUR COOK, Cor. Secy.

DAHLIA SOCIETY OF NEW JERSEY

This society was launched with great enthusiasm on March 14th last at the International Flower Show. Some eighty members were enrolled at once, a Constitution and By-Laws were adopted and the following officers elected:

President, Mrs. Charles H. Stout, Short Hills, N. J.; First Vice-President, William H. Waite, Rumson, N. J.; Second Vice-President, Warren W. Maytrott, Vineland, N. J.; Third Vice-President, Charles E. Walker, Paterson, N. J.; Fourth Vice-President, Mrs. J. J. ... Secretary-Treasurer, Mrs. Stephen C. Van Hoesen, Fanwood, N. J.

USE
SUNOCO SPRAYING OIL
 FOR
Box Bush Leaf Miner

Box bushes, to prevent damage from this pest, should be treated in early May, as the adult flies begin to emerge from the foliage. Circulars on this pest and method of treatment mailed free upon application. Ninety per cent control possible.

1 gal. can, \$1.00; 5 gal. can, \$4.00; 15 gal., \$10.50.

ANDORRA NURSERIES, Inc. CHESTNUT HILL PENNSYLVANIA

Rahway, N. J.; George Praster, Montclair, N. J.; Mrs. F. S. Fisher, Trenton, N. J.; Robert L. Roe, Hobokus, N. J.; Charles H. Totty, Madison, N. J. The first regular meeting took place in the Council Chamber of the City Hall in Newark, N. J., when plans for a field meeting in August and the first annual show were discussed. The latter will be held in Newark in the middle of September—date and place to be announced shortly.

Dr. Marshall A. Howe delivered a most instructive illustrated lecture.

This young society has already doubled its membership and shows great promise. Its slogan is "Quality above Quantity" and its object, as incorporated in the Constitution is:

"To stimulate the interest in dahlias; to encourage the amateur; to assist the grower to keep a high standard for varieties originated and grown in the State of New Jersey."

It has affiliated with the American Dahlia Society and plans to assist the latter by taking over all problems relating to the dahlia within the State of New Jersey.

THE FLOWER SHOW

NO ONE could long be a pessimist in the presence of such a splendor of flowers as filled the Grand Central Palace at the Annual Flower Show. If Solomon in all his glory was not arrayed like a single lily of the field, what comparison is to be found for the masses of color which have been made to blossom from like root and stalk under human cultivation? Man has been enjoined by the Great Teacher to forget his anxiety about tomorrow and to fortify his little faith by beholding how the wild flowers are clothed. But the moral of the Flower Show is that if man can in co-operation with the Creator work such miracles in the culture of flowers, what ought he not to do in the cultivation of the faculties of children or even in the improvement of his own perennial self?

But quite aside from the moral, the sheer enjoyment of these flowers (which have doubtless found their way into hospitals, schools and the homes of the shut-ins before they were "cast into the oven") makes for a paradisaical state so long as they last and leaves a wholesome memory of color or perfume that will last longer than the flowers themselves. A flower show would be the last place on earth in which to start a riot or to blaspheme an enemy. It was because of this effect of flowers in "destroying all contaminations" that Buddha put first among his seven shops in the "City of Righteousness" and in the "Street of the Earnest Meditations" a flower-shop; for this was the list of his shops: a Flower-shop, a Perfume-shop, a Fruit-shop, a Medicine-shop, an Herb-shop, an Ambrosia-shop, a Jewel-shop—and a General-shop.

Into the Flower-shop one is commanded by Buddha to go and "buy a subject for meditation." And if there is one thing we need in our Western urban life more than another, it is that for which Buddha's Flower-shop furnished delectable subjects—meditation. So is "deliverance" promised even from the muck and refuse of New York streets, far from Eden and Buddha's City, where children beg for tickets to see the gardens, far more beautiful than the one could have been in the midst of which our scriptural ancestors were placed and from which they were driven forth to earn their bread in the sweat of their faces. Through a culture of which the Flower Show gives but the exquisite simile, man finds his way toward another paradise.—*The New York Times*.

Range of V-Bar Greenhouses Built for Mr. Emil Winters, Pittsburgh, Pa.

"One Good Job Begets Another"

To the National Association of Gardeners:—Greetings

While at the Annual Convention of the Association you will have a good opportunity to see for yourself why so many of the best gardeners in the country recommend Lutton V-Bar Greenhouses.

In Pittsburgh and Sewickley we have built V-Bar Greenhouses for the following:

- Mrs. J. D. Lyons, Sewickley, Pa. John Barnett, Gardener
- Mr. H. L. Mason, Sewickley, Pa. James Murphy, Gardener.
- Mr. E. A. Woods, Sewickley, Pa. Henry Gibson, Gardener
- Col. J. M. Schoonmaker, Sewickley, Pa.—John Carman, Gardener.
- Mr. B. F. Jones, Jr., Sewickley, Pa. H. Baumgarten, Gardener.
- Mr. W. S. Mitchell, Pittsburgh, Pa. Robt. Ladner, Gardener
- Mr. Emil Winter, Pittsburgh, Pa. Otto Rost, Gardener
- Mr. E. M. Herr, Pittsburgh, Pa.
- Mr. Geo. Mesta, Pittsburgh, Pa.

The Lutton V-Bar type of greenhouse construction is the most durable, lightest, strongest, most sanitary and efficient type of greenhouse built. There is a complete galvanized iron and steel framework and the glass does not touch the metal but rests in a cypress cushion and all condensation is properly taken care of.

THE GARDEN

Our England is a garden that is full of stately views,
 Of borders, beds, and shrubberies, and lawns and avenues,
 With statues on the terraces and peacocks strutting by;
 But the glory of the garden lies in more than meets the eye.
 Except when seeds are planted and we shout to scare the birds,
 The glory of the garden it abideth not in words.
 And some can pot begonias, and some can bud a rose,
 And some are hardly fit to trust with anything that grows;
 But they can roll and trim the lawns and sift the sand and loam,
 For the glory of the garden occupieth all who come.
 For the glory of the garden glorieth every one.
 Our Adam was a gardener, and God who made him sees
 That half a proper gardener's work is done upon his knees;
 So when your work is finished, you can wash your hands and pray
 For the glory of the garden that it may not pass away!
 And the glory of the garden it shall never pass away.—KIPLING.

*The Insecticide that
Kills plant Lice
of many species.*

The Insecticide of Recognized Merit for Greenhouse and Garden

APHINE is a concentrated material—mixes readily in water—efficient in its action—easily applied—free of the disagreeable odors and features of most insecticides—excellent as a wash for decorative plants.

FOR THE GARDEN—As a remedy against all sap sucking insects infesting flowers, fruits and vegetables, APHINE is most effective.

FOR THE GREENHOUSE

—Applied at regular intervals (once each week or ten days) APHINE will keep plants in the greenhouse and conservatory free of insect pests.

FUNGINE—For mildew, rust and other blights affecting flowers, fruits and vegetables.

VERMINE—For worms and insects infesting the soil.

The Tribute of William Turner to Davey Tree Surgery

Rumson, New Jersey.

THE DAVEY TREE EXPERT CO., KENT, OHIO.

Dear Sirs:

Having at different periods the opportunity of witnessing the methods of your work here on Mr. Bertram H. Borden's estate at Rumson, New Jersey, and have found your men to be thoroughly expert with all work in tree surgery. The accompanied photo will speak plainer than anything I can say, as it will be noticed clearly the cavity that was in the tree before treated four years ago is practically healed over, I would say a monument to the Davey Tree Surgery.

WM. TURNER,
Supt. to Bertram H. Borden.

To save fine old trees every gardener and estate superintendent needs highly skilled assistants. Many, like Mr. Turner, protect their trees by Davey Tree Surgery—a science developed by a generation of study and experience. A careful examination of your tree will be made by appointment.

THE DAVEY TREE EXPERT CO., Inc., 306 Elm Street, Kent, Ohio.

Things and Thoughts of the Garden

WILLIAM N. CRAIG

THERE appears to be a steadily increasing interest in hardy roses in all sections of the United States, and the various "Rose Pilgrimages" planned by the American Rose Society have done not a little to enthuse amateur growers in the Queen of Flowers. Those of us who rarely go afield and do not know what others are growing, or are doing, are apt to lead too self-satisfied lives and to have a somewhat exaggerated idea of our own productions. It is the very best form of horticultural education to do some visiting at rose time and make mental and pencil notes which are bound to prove helpful. I have attended outings where dahlias, gladioli, peonies, iris and Spring bulbous plants were in season but with none of them did the enthusiasm at all equal that manifested in hardy roses. There is such an infinite range of colors and types which are being constantly added to, and the wonderful additions to the hybrid tea, polyantha, rambler, Pernetiana classes and species keep interest keyed up.

The great interest today is divided between the hybrid teas and ramblers; the hybrid perpetuals are year by year being more pushed to the wall. In some respects this is regrettable as for our colder states they are by far the most dependable of our bush roses as they are much hardier than the hybrid teas and are longer lived. The name "perpetual" is something, however, of a misnomer, as with a few exceptions such as Frau Karl Druschki, Mrs. John Laing, and Mrs. R. G. Sharman Crawford, they carry one good crop of flowers in early Summer and bloom rather sparingly thereafter. I have had many plants of hybrid perpetuals which have lived from fifteen to twenty-five years and in some cases even more, in the immediate vicinity of Boston with no Winter protection but soil, which by the way is far the best covering in cold latitudes. This is something we cannot say of the beautiful but more tender hybrid teas. It is true that Gruss an Teplitz, Mmc. Caroline Testout and one or two others are as dependable as the hybrid perpetuals, but they are decided exceptions to the general rule.

A hardier type of rose which will be a persistent bloomer and adaptable for culture in our cold northern states would seem to be entirely possible if hybridizers would use the hardiest possible stocks. In the great number of species of roses, both native and foreign, surely one can be found which will satisfy our needs in this respect. We may not be able to get the big handsome exhibition roses we are well acquainted with, and possibly the orange, apricot, old rose, and some other delightful shades would have to be eliminated and blooms of a moderate size, in

many cases carried in clusters, would be given, but some day, it may be nearly half a century away, we shall have such a race which will thrive in almost every state in the Union. There is a great field for hybridizers, and there will surely arise men of the type of the late lamented Dr. Van Fleet, and M. H. Walsh to give us a real American race of hardy roses.

*

The passage of Quarantine 37 with the debarment of all roses except a very limited number of the newer sorts has naturally stimulated rose propagation in America. California is now the state par excellence for rose production; plants sent from there are of good size, although usually budded much too high. The trouble is that while the manetti stock is now used in the main, there is an evident tendency to speed up production by using such tender stocks as Rose odorata, which can be propagated with remarkable rapidity, and while these roses will no doubt prove satisfactory in the balmy sections of the country they are sure to prove most disappointing in the colder states, and are unlikely to prove of any value in that Atlantic coast section where horticulture has a great number of devotees. It is a fact that much Californian stock is now being planted outdoors in the East; personally I would very much prefer stock budded in New Jersey or some more vigorous climate as more likely to give satisfaction.

Another type of rose has come to the front during the past year or two, and much of it is being advertised and sold for "field grown stock." I refer to greenhouse roses which have done service for several years in beds or benches and were formerly thrown away and burned. These plants are now being dried off and rested for a few weeks, pruned back and sold for hardy stock. I have known these roses to winter over under favorable conditions and give a very good account of themselves the second and third seasons. They can always be depended upon to produce a fine late Summer and Fall crop the same year they are planted. But it is too much to hope that plants which have been forced in greenhouses for, in some cases as many as six years, will prove as satisfactory in the garden as outdoor grown stock. One firm of rose specialists advised me that they had sold 25,000 of these old forced plants as "hardy garden roses" at a flat rate of \$5 per dozen. I consider this a distinctly dishonest practice, one which will do much towards discouraging the culture of roses in the garden. Still another large rose specialist wholesales this discarded stock at \$100 per 1,000, and in small lots at \$3 per dozen. This grower, however, adopts

the more honorable policy of telling purchasers that these plants are good for one year and can then be discarded. As such I can most heartily recommend them.

The Pernetiana type of roses of which Soleil d'Or, introduced nearly a quarter of a century ago is probably the oldest member, has come very much to the fore the last few years. They were originated by that skillful French rosarian, M. Pernet Ducher, from whose hands have come so many good garden roses. By utilizing the brilliant Austrian Copper as one of the parents he has given us a class of roses carrying flowers of exceptionally rich and unusual color, particularly in the copper and apricot shades. Amongst the yellow shades of these, which I have seen in very good condition this season in Massachusetts are Constance, Soleil d'Or, and that wonderful variety, Souvenir de Claudius Pernet, which has attracted more attention than any new introduction in late years. The value of this latter rose in the garden has yet to be demonstrated. Like all of the Pernetiana varieties it is quite susceptible to black spot. Dust spraying is more effective in combating this than any of the liquid fungicides and it is much more easily applied. I have found that by using eight parts of sulphur and one each of lime and dry arsenate of lead, and dusting the roses susceptible to black spot once in two weeks during the flowering season, this unsightly disease can be largely eliminated. This dust spraying has proved very effective in controlling the sooty blotch fungus on such apples as MacIntosh Red and for plums and peaches; in these latter cases omitting the arsenate of lead, which controls certain leaf eating insects on the roses, and using an additional part of lime in its stead.

Harking back to the Pernetiana roses there are a number of copper or apricot shades which are doing quite well in some northern gardens. I doubt, however, whether these will prove long lived, even under favorable conditions, though their exquisite colors will create a big demand for them even if they only last two or three years. Specially fine amongst these the present season are Juliet, Mme. Edouard Herriott (better known as the "Daily Mail Rose"), Miss Lolita Armour, Louise Catherine Breslau, and Arthur R. Goodwin, the newer Souvenir de George Beckwith and Souvenir de Georges Pernet are both lovely, but more time is needed to try them out.

There are now many beautiful and distinct species of roses that amateurs would do well to take up, as they are in nearly all cases of more vigorous habit than the bush roses; they are not adapted for culture in beds in the same way. A sloping bank devoted to the various species is ideal or they have a place in the shrubbery border. Some of these species flower very early but by growing a number of kinds quite a long succession of bloom may be had and many are very attractive when in fruit. *R. Hugonis* since its introduction has been in tremendous demand and is certainly a lovely yellow rose. It is the only really dependable yellow, shrubby habited rose we have apart from the Persian Yellow, Austrian Copper, and Harrison's Yellow. A new Asiatic species at the Arnold Arboretum, *Rosa Ecae* is very promising and flowers even earlier than *R. Hugonis* with somewhat smaller and paler yellow colored flowers. It is also a more vigorous grower and its frequent foliage is a great attraction. This rose will probably be offered in the trade in a moderate way next season. *R. rubrifolia*, a European variety, is very striking in any collection of roses on account of its foliage being tinted with purplish red. *R. setigera*, the well known "Prairie Rose," is splendid for mass effects, as *R. Wichuraiana*, the "Memorial Rose," is for covering bare banks. *Rosa spinosissima altaica* has been dubbed the "Northern Cherokee Rose." It is a very superior form

of the Scotch Rose and carries lovely single white flowers three inches in diameter. *R. multiflora*, carrying clusters of pure white flowers, is well known and deservedly popular, not so well known is *R. multiflora* *Catheysensis*, a very vigorous grower with clear pink flowers produced in great profusion. *Rosa omeiensis* from Western China is offered in the trade and is one of the best of the newer species, of vigorous habit, its pure white flowers followed by very attractive fruits. These are but a few of the many beautiful species of roses. Particularly striking in the Arnold Arboretum collection at the time of the visit by members of the American Rose Society was *Rosa Arnoldiana*, raised by the late Jackson Dawson by crossing *Rugosa* and the old popular hybrid perpetual, General Jacqueminot. This hybrid is of erect habit, very vigorous, and is smothered with large single or semi-double flowers which are bright red in color; this fine variety is offered in the trade.

A reader of the GARDENER'S CHRONICLE of America has written to me in regards to remarks made in the May issue about one of the species of tulip, *Turkestanica*, throwing several flowers to the bulb, and states that he had noted the same thing in the case of *La Tulipe Noire*, a well known and popular Darwin *Præstan*, another species, will often throw several flowers to the bulb. The tulip, however, which will the most consistently produce several flowers to the bulb is another inexpensive and popular Darwin, usually called Gretchen, but occasionally Margaret. This pink Darwin is a splendid bedder and the abundance of small side flowers practically hides the soil from view. One or two varieties of the early forcing tulips show the tendency to throw side flowers, but at this time I cannot recall the particular varieties. For bedding purposes the production of several shorter spiked and smaller flowers circling the main stem is a decided advantage, although forcers of tulips for cutting would no doubt prefer single flowers to a bulb. There are no doubt other readers of the CHRONICLE who have noticed the tendency of certain tulips to throw several flowers to a bulb and their experience would be worth recording.

Very beautiful in early July are the Delphiniums in the hardy perennial borders. They come in an almost infinite range of blue shades. Associated with *Lilium candidum* or that newer but most satisfactory garden lily, *L. regale*, the combination is almost irresistible. There are now many beautiful named hybrids of *D. formosum* which produce the most stately spikes. These are made more a feature of in Great Britain than here, and Americans visiting the big Summer shows over there marvel at the size and magnificence of the spikes exhibited. The British climate is more of an ideal one than ours for the culture of Delphiniums and the bulk of herbaceous perennials, as it has a much lower mean temperature, more frequent rains, and only occasional spells of sizzling heat such as we are subjected to here but their ease of culture is such that anyone can soon have a stunning show if he will care for the seedlings.

Hardy larkspurs have jumped into favor very much in recent years for forcing purposes and remarkably good spikes were to be seen at the New York show in the middle of March. Forcers of these flowers have their troubles with stems damping off which I will not go into now, and outdoor growers also have some worries when they see stems throwing deformed flowers and many leaves becoming black in color. Plants which have been undivided for several years are most susceptible to this disease. Diseased stalks should be cut off and burned

(Continued on page 174)

In the Garden and in the Greenhouse

GEORGE F. STEWART

IN THE GARDEN

LATE July and early August are generally quite trying times in the garden. It is probably the hottest part of the whole year, and thunderstorms are frequent, accompanied by torrential rains, which very often do irreparable damage in the garden, unless staking has been properly attended to. Even then, some plants will be considerably damaged by the wind and rain. How often the gardener will have the place in first class shape, with a good display of flowers in the beds and borders, when one of these sudden storms will come up, washing out walks, throwing mud over the plants, and destroying the floral display. My fellow gardeners all have had this experience, more or less frequently, and it takes a philosopher indeed to keep calm on such trying occasions.

The main task in the herbaceous borders from now on will be to keep the soil around the plants cultivated, cutting down plants that have finished flowering, and filling in the gaps with suitable ones from the supply garden. Quite large plants of various annuals may be moved for this purpose. They are better if quite dry at the roots, when they are dug up, but when they are replanted, they should be given a thorough watering. If they are in a dry condition when moved, it is astonishing how little they mind the change. An occasional application of fertilizer helps all the plants, as the manuring that has been done in the Spring very soon becomes exhausted with frequent waterings.

This is a good time of the year to look over the shrubbery. Plants may be getting overcrowded and in the Fall may need transplanting. Dahlias need to be well staked as they are likely to be top heavy and unless they are well tied up storms may break them down. They also need to be sprayed for insects, as their flowering qualities are easily ruined if this is not attended to. As soon as they set bud, applications of fertilizer may also be given. Cultivate them lightly on the surface and water if they get very dry.

See that *Campanula medium* and other biennials are transplanted, allowing them plenty of space between the plants as they do not winter well if over crowded.

By the end of July sow seeds of pansies, daisies, and forget-me-nots for next Spring.

Give the hybrid tea roses plenty of plant food, and waterings with manure water, if plenty of outdoor roses are expected in the Fall. They also need frequent syringings with Fungine to prevent mildew and black spot. To have fine outdoor rose displays as was seen at our convention last year, the plants need as much attention, as is given to those grown on benches indoors. Look over the Rambler roses and cut out a good deal of the old hard wood. Give them also plenty of plant food, to build up the young growths for next year. Give them a tie in occasionally to support the young growths. Pyrethrum if kept from going to seed will flower a second time. This also applies to *Gaillardias* and *Salvia pratensis*, etc. Many outdoor plants are affected by red spider and evergreens especially are better if sprayed with some insecticide as soon as they put in their appearance.

Work in the formal garden will now be routine—picking off dead flowers and leaves, and edging around the beds. Some of the geranium plants may be inclined to run out on to the grass. These may be cut back and used for cuttings. When weeding stir the surface of the beds lightly.

Work in the vegetable garden will consist of hoeing, cultivating and dusting for fungous and insect pests.

Keep up sowings of beans as late as August 15. Sometimes the last sowing is nipped by an early frost, but it is always worth taking a chance. Corn may be planted as late as the last of July. Like beans, it is liable to be injured with frost if it strikes early, especially on low ground. Corn enjoys rich land and plenty of cultivation. The corn borer is very troublesome around here, but I am told that if the tassels are sprayed with arsenate of lead it kills them. Of course, it ruins the stalks for fodder, which is a detriment.

Late celery should be planted after the peas are past bearing. Spraying with Bordeaux should be done to prevent rust, although last year it did not seem to work out. But then, it was an exceptionally wet season. A quick maturing crop may be planted between the rows, lettuce, radishes, etc.

Late cabbages and cauliflower may be planted out as the peas are passing out of crop. A good coating of Scotch soot should be dusted on the rows before planting as root maggots and such like are not happy in its vicinity.

Spray or dust the asparagus bed for the asparagus beetle has been troublesome lately. Be sure to feed this crop heavily while it is growing, which determines the quality next year.

Sow Fall lettuce about the first week in August in a good rich piece of land. Spinach for Fall use may be sown about August 10. It is generally ready to use when the New Zealand Spinach has been cut down by early frost and continues until hard frost.

After the strawberries have finished bearing, plants that are to be carried over should be given a thorough cleaning and fertilizing with bone meal and acid phosphate. Wood ashes also seem to agree well with them. All runners should be removed, except those which are required for forcing next Winter, and planting a new plantation. The runners for forcing should be pegged on the top of small pots filled with loam so that they may get established quickly. In fact, if one has the time, those that are to be planted out are better if treated the same way, as they also establish themselves much faster. A good coating of hog manure is excellent for the land they are to be planted on, which preferably has been broken up sod land in the Spring.

Watch out for any outbreak of the potato bug. Spray for it and also spray for blight. Early planted varieties should now be ready to use, but too many should not be dug at a time, as they will yet continue to grow, just enough for daily use, unless one has to ship them a distance.

As soon as the raspberries have been picked, cut back the canes close to the ground and thin out the young ones, four or five to a plant is enough to leave. Of course, this does not apply to the late fruiting varieties. Go over the fruit trees, when time allows. Pinch back the young growths to four or five leaves except the points of the branches. Take note of any tree that is going too much to wood without bearing fruit, and before it freezes in the Fall give it a good root pruning. Be especially careful to get at any straight tap root and cut it well back.

IN THE GREENHOUSE

The greenhouse requires a good deal of attention this month as a foundation is laid for many plants and flowers that will be required next Winter. It is also an opportune

time of the year to make any repairs that are needed. As time permits, thorough cleaning should be given and frequent dustings of lime under the benches which tends to keep the atmosphere sweet, and also at the same time, kill any slugs that are around. See that the pipes and heating plant is in good repair, as very soon—on wet nights—a little fire heat will be beneficial to counteract dampness.

The chrysanthemums now demand considerable attention. Disbudding of side growths must not be neglected on the single stem plants, as in a very short while they would take the strength from the main stem. Feed them liberally with plant foods in variety, a little at a time and often is better than in large doses. Look out for the least tendency of any plant to turn yellow on the tips, and stop giving plant food, until it regains a normal color, also keep it on the dry side. Syringing the leaves with Scotch soot water adds to the lustre of the foliage. Stop pinching the bush plants about the first of August, and add a few stakes to steady them. After seeing the trellis trained specimen plants at the New York Show last Fall, personally, I have no use for them, they are not a bit natural looking. A well staked plant in my opinion preserves the bush form far better, and is much more pleasing to the eye. Nice dwarf plants in eight-inch pans we find very useful around Christmas. Secure a good batch of cuttings by the end of July, which root outdoors in about three weeks. Then pan a dozen cuttings of equal size and even root action and set them close up to the glass. They will flower about twelve inches high. There are some varieties that never flower, rooted so late in the season, but we have found the following answer the purpose well: E. D. Godfrey, Gaza, Miss Isabelle, Jane Inglis, Mrs. Buckingham, November Glow, Margaret Waite, William Lincoln, Wells' late pink.

We have plants of Allamanda, Ixora, Hoya, Stephanotis and Dipladenia in flower at the present time. A little plant food will keep them growing well into the Fall. They deserve the best of care as they make fine specimen plants.

As Achimenes and Gloxinias pass out of flower, gradually withhold water from them until they are ripened off. Select a dry, warm corner for them as Fall approaches for they will not stand cold even when dried off.

Get the first lot of Frezias started about the end of July. Home ripened bulbs force better for Christmas than those we buy in the seed stores. They like a good leafy, sandy soil and may be left outdoors until they start. Then if put on a shelf in a temperature around sixty degrees, they will come in for Christmas. Secure cuttings of Fuchsias during the last of July. Strong, soft tips make nice specimens by next May, if kept growing all Winter, and are most useful plants throughout the Summer.

The young Cyclamen plants need close watching to have good plants next Winter. Give them a leafy, fibrous loam, fairly rich. They seem to enjoy dried cow manure in the compost, with charcoal and sand to keep it sweet and open. Don't forget to get fresh seeds of Cyclamen in August. Space them equally in a flat filled with fibery loam, having plenty of leaves mixed through it and adding sand and charcoal to keep it open. They do not need to be disturbed until several leaves are formed.

Sow early in August seeds of Calendula, Dimorphotheca, Lupine Hartwegii, white and blue; Stocks and other annuals that are suitable for Winter flowering.

Lachenalia Nelsonii is a nice bulbous plant for Winter flowering. Start the bulbs in August, and leave them outdoors until there is danger of frost. They look well in either small pots or ten or twelve bulbs to an eight-inch pan.

Put in batches of Poinsettia cuttings as soon as they are three inches long, up to the end of August.

Secure bulbs of Polyanthus Narcissi early as possible; they force very early and fill in a gap when flowers are scarce. Besides the varieties, Paper White, Grandiflora and Grand Soleil d'Or, the variety Gloriosa is very pretty. Some prefer it to Paper White, which has been so popular for so many years. If an early tulip is wanted for forcing, Duc Van Thol is about the first that will come.

See that hard wood plants are well watered, as now they root freely and on bright days will dry out often. Frequent waterings exhaust the soil in the pots and stimulation with liquid and other manures is necessary.

Syringe the Camellias well when they need water but do not allow them to get into a wet, soggy condition as it is certain death to the roots. Withhold plant food as soon as the flower buds are set.

Avoid overcrowding plants in the tropical house. They need plenty of room to develop their foliage which is the chief beauty of one section of these plants. By this time of year the compost will be exhausted if they have been rooting freely, and stimulation must be applied to keep up an even growth until the end of the season. Thin out all weak fronds from the center of the adiantum ferns, giving the stronger fronds a chance for a more free circulation of air through them. The slug is an enemy that will soon ruin a maidenhair fern and it requires close watching to keep rid of it. Sprinkle the benches with lime and put a dusting of dry, soft-coal soot around the inside of the rim of the receptacle. This method will generally take care of them, but it has to be done repeatedly.

Have a good variety of various kinds of ferns and Selaginellas. There is nothing more decorative when a group of plants is arranged than the various shades of green of these plants. A well grown, individual specimen of any one of them is always an attraction. The time was when no greenhouse was complete, unless an apartment was set apart for a collection of ferns, and now there are many species which we have not seen for years. Plants in the greenhouse are getting well rooted, and will on bright days, dry out much more often than early in the season. So watch them closely. Dendrobium thyrsiflorum, tensiflorum and Farmeri will now be growing freely but do not overwater until the new roots appear. Some of Dendrobium Wardianum and Primulinum will be finishing their growths and may be removed to a more airy house. Do not withhold water as long as the leaves are green; diminishing it gradually as the leaves begin to get yellow. Cologyne cristata needs plenty of water at this stage of growth and frequent applications of weak liquid manure will also help to strengthen the bulbs.

Cattleya Bowringiana as the new roots appear, will also take more water. This Cattleya, however, will do with less water than many others of the same genus. It is better not to let the water lodge in the center of the young growths. Lælia autumnalis is slow at starting into growth, but develops rapidly after it has made a start. This Lælia likes plenty of light and should be only slightly shaded from the strong sunshine. Weak applications of manure water will benefit nearly all orchids after they begin making new roots, until the completion of growth. They do not like hard water and I believe that the lack of using rain water is more generally the cause of non-success in orchid growing than any other cause.

As soon as melons show the least sign of ripening, stop using any stimulant or liquid manure in any form. Those that have set their fruits, and are in active growth, will take plenty of food. Peaches and nectarines that are clear of fruit should be given a good syringing every bright day. Those that are ripening will have to be left alone until the fruit is picked. Pot fruit which has had its crop picked may now be potted, if necessary. Rub the ball

Ornamental Vines, Their Cultivation and Use

DR. E. BADE

THE use of ornamental vines in the garden depends upon the purpose which they are to serve. Sometimes it is an old tree upon which they are to climb; at times it may be the fence which is entwined with their leaves and their flowers; in another place they cover the bare walls with their foliage; or they provide airy and shady resting places when they spread their tendrils over summerhouse and porch. At times they form living gar-

order; this is also true for those plants used for porch climbers. They should not escape which is the case with far the greater number of our vines. Species of *Caprifolium*, *Celastrus*, *Menispermum*, are not to be recommended for this purpose since these, in the course of the years, form thick, rope-like stems, and in addition to this *Caprifolium* (Honeysuckle) has the disadvantage of being bare of leaves in its lower and central parts, while

Rosa

Caprifolium

lands which are very effective and attractive, if they are placed in the right spot. For this latter purpose they are too seldom used, and still how simple and easy is their

the flowers are formed at the tips where they are difficult to see. Beautiful, on the other hand, is *Glycine* (*Wistaria*) with its blue grapelike flowers and feathered leaves.

Glycine

Clematis

cultivation. Poles placed into the soil equal distances apart so that the first protrudes about half a yard, the second one yard, and the next half a yard again, are connected with galvanized wire. The vines, whether annual or perennial climbers makes no difference, are trained along this wire.

There are but few climbers suitable for planting around summerhouses. Such climbers should be easily kept in

Other desirable climbers for porch or summerhouse are *Aristolochia*, *Ampelopsis*, *Clematis*, the rambling rose, the grape, and the wild grape.

Annual vines are not recommended for the summerhouse as they take too long before they are fully developed, although some of them are exceedingly rapid growers. These are propagated from seeds.

Climbers suitable for shady places are *Aristolochia*,

Celastrus, Ampelopsis, Humulus lupulus, Hedera helix, Akelia, Lonicera. For northern exposures Clematis jackmanni, Cl. henryci, Ampelopsis veitchii, Hedera helix are best adapted. Ampelopsis engelmanni, Dioscorea barbata, Lycium, Periploca do very well when placed towards the east. But sunny places should be selected for Begonia radicans, Clematis paniculata, Lonicera, and the rose.

Such perennial plants are propagated through seeds, shoots, or cuttings as the case may be. Few of them desire a special soil. many do well in any fertile soil.

The beautiful effect of the climbing vines when trailing around the house is well known but of its practical value a division of opinion exists, both in builder and in planter circles. Some believe that vine covered walls do not allow air, sunshine, nor light to reach it, and so, because of the dense foliage, tend to keep and store moisture. Mice also are said to use the thicker branches as a bridge to enter the house. Other people believe that the vines keep the moisture away from the walls since they penetrate, with their aerial roots, the cracks and crannies of the wall and draw all available moisture out. At any rate, this divergence of opinion strengthens the fact that regional climatic conditions must be studied before it can be said that it is or is not advisable to plant climbing vines. A damp house will seldom if ever be freed from its moisture when such plants are planted, and so it is impossible for these plants to moisten the walls.

A little known and unappreciated annual climber is the "Wild Balsam Apple" (*Echinocystis lobata*). It is a very rapid grower and produces a dense growth of foliage. This beautiful and decorative climber produces both flowers and fruit at the same time. The tiny short stemmed flowers appear in close clusters. The somewhat cucumber-shaped fruit are the size of a pigeon egg and are protected with soft spines. These plants occur wild in a heavy type of soil along river banks and bottoms in New England, Pennsylvania, and westward. It climbs into trees to a height of from fifteen to twenty feet. In the garden they require a sunny place, are sown in the Spring at the desired spot, and are watered during the dry parts of the Summer.

THE LABURNUMS

LABURNUMS, small European trees or large shrubs, sometimes called "Golden Rain," can furnish gardens in June and July with the handsomest yellow flowered trees which can be grown in this climate. The best known Laburnum in this country is *Laburnum anagyroides*, or as it is more often called *Laburnum vulgare*. This is a native of central and southern Europe and a shapely tree from twenty to thirty feet in height. It is one of the most generally planted and popular exotic plants in England and probably was brought early to the United States where it has been more generally planted than the other Laburnums. Although not always perfectly hardy in Massachusetts large plants are occasionally found in the neighborhood of Boston and these are now covered with their drooping racemes of golden colored flowers. A number of varieties of *Laburnum anagyroides* are propagated in European nurseries but these are curiosities and certainly not better as garden plants than the type of the species. One of the most distinct of the abnormal forms, var. *bullatum*, with its curiously twisted and contorted leaflets is now in bloom in the Arboretum. The Scotch Laburnum (*L. alpinum*), probably so called because it is a most cultivated and favorite garden plant in Scotland, flowers later than *L. anagyroides* and is a hardier plant in this part of the country with longer racemes of flowers. When the plants growing in the Arboretum are covered with their long drooping flower clusters they are objects

of great beauty and it is surprising how little this plant is known to American garden makers. Another Laburnum, *L. Watereri*, a natural hybrid between *L. alpinum* and *L. anagyroides*, is intermediate between its parents in botanical characters and in the time of flowering, and is a beautiful small tree better suited to the New England climate than *L. anagyroides*, and a good plant for the decoration of a June garden. *L. Watereri* appears to be little known in this country. The third species of Laburnum, *L. caramanicum*, a native of Greece and Asia Minor, has been planted in the Arboretum but has not proved hardy here. *Arnold Arboretum Bulletin*.

NEW BABY RAMBLER, CHATILLON ROSE

A NEW baby rambler, Chatillon Rose, originated by August Nonnin, Paris, France, will soon be disseminated in this country by Henry A. Dreer, Inc., Philadelphia. The illustration is of a plant in a six inch pot. It makes

The Chatillon Rose

a compact, bushy plant, literally covered with clusters of cerise pink blossoms, centered with large white eyes. This rambler should become quite a favorite for decorative purposes.

THINGS AND THOUGHTS OF THE GARDEN

(Continued from page 173)

for there is little doubt but that this fungus carries over in the soil for one or more years just as many other ailments of a fungoid nature do. What can be done to prevent or check it. Eight parts of sulphur to two parts of lime should be dusted through the plants from the time they are a foot high until they near the flowering stage. This same remedy should be used on *Lilium candidum* often seen so disfigured with disease in the garden. *D. belladonna* is somewhat less subject to disease than *D. formosum*, but is by no means immune. *D. chinensis* which is less of a true perennial than the other two, seems to be practically immune.

Some Impressions of Chelsea Show

ARTHUR T. JOHNSON, F. R. H. S.

THE Royal Horticultural Society's Spring Meeting, annually held in the picturesque grounds of Chelsea Hospital in the heart of London, is the Mecca of all garden lovers. This year the weather could hardly have been more atrocious, but not the downpour which prevailed over the first two days, nor yet the oceans of mud, deterred the thousands who had made up their minds, come what may, to attend this great event. Indeed, the gardening public flocked in the tens of thousands. They came not only from the remotest parts of these isles of Britain and Ireland but from the Continent of Europe and even far-off America was not unrepresented. They came, these pilgrims, to see flowers and they saw them in all the glory of that perfection which is the hallmark of the professional grower's and exhibitor's skill. But here were not only the choicest collections of those great nurseries of the Old Country which have a world-wide reputation, but the priceless gems of many a private garden whose names have rarely, if ever, figured in any trade list and whose faces the vast majority of those present had never before seen.

As indicating the trend of public interest in gardening matters it was noteworthy that the greatest crowds were those that thronged around the exhibits of alpine and other rock plants, many of which were tastefully shown in a natural setting of cleverly-constructed bits of rock-work erected on the staging. Here one noticed how well many of the old and well-tried plants are still holding their own among the new comers, there being extensive displays of those taller Encrusted Saxifrages most of us know so well, the Phloxes of the alpine section, Sedums and Linarias, the more familiar Gentians, the Cheiranthuses, Aubretias, Achilleas, Dianthus and representatives of most other well-known groups. Among this bewildering array of color, to mention but one or two of the choicer things, there were some superb groups of that exquisite Columbine, *Aquilegia glandulosa*, surely the most precious of its race, though the Rocky Mountain species, *A. cœrulea*, runs it close. *Dianthus* "Cæsar's Mantle," an old but now rare plant, was here, and on at least one stand there was a fine carpet of *D. Fosteri*, a brilliant carmine rock Pink with a lead-blue eye. *D. "Spencer Bickham,"* a dazzling carmine, could hardly escape notice and one saw some pretty patches of the true *D. Freynii* and sub-*acaulis*. Here and there the vivid cerise of that little carpeting plant, *Heeria elegans*, from Mexico, made an amazing splash of color. *Phlox Canadensis*, Lapham's var., in almost a plumbago blue, was a striking object, and both the Globe Flowers (*Trollius*) and the double forms of *Meconopsis cambrica* impressed one with their increasing size, substance and depth of colors. There were some admirable groupings of the lovely *Roscoea cautilioides*, of hardy *Cypripediums* and such little Irises as *gracilis* and the tiny *cristata* and *lacustris* which attracted much attention. *Ourisia coccinea*, a bog plant in bright scarlet and several *Dianthus neglectus* hybrids were very striking. Some pretty groups of the somewhat difficult *Houstonias* were among the more notable subjects, there were several mats of the Himalayan *Parochetus communis*, whose pea-shaped flowers are a vivid gentian blue, and one noted the pure white, the pink and the golden

leaved (var. *Treherne*) forms of the common *Veronica rupestris* (*prostrata*) which, though not new, are still uncommon.

Among the many *Violas*, other than bedding varieties, the lovely *V. gracilis* was as supreme as ever, and the white form (Clarence Elliott's var.) the yellow (Perry's Yellow) lavender-blue ("*Lady Crisp*") and the jet black ("*Black Knight*"), with a golden eye were some of the most charming of the *gracilis* type. I also noted some good specimens of *V. bosniaca*, *V. calcarata*, *V. pedata* and the curious Tree Violet, *V. arborea*. That splendid *Armeria*, Bees' "*Ruby Thrift*," with very large flowers on two-foot stems, was a conspicuous object on many stands, and the fifteen-inch *A. cephalotes rubra*, whose equally brilliant heads are carried on rigid, upright stems, attracted considerable notice. Here and there one came across the blazing crimson of *Pentstemon rupicola* (*Davidsonii*) and the gentle lavender of *P. Scouleri*. *Linum narbonnense* was shown in fine form, its sheaves of intense azure contrasting with the glacier whiteness of *L. monogynum*. There were some splendid drifts of *Dryas octopetala*, that first-rate Rocky Mountain Avens, and *Lithospermum prostratum*, "*Heavenly Blue*," *petrae*, *graminifolium* and others were all on view in the best of condition. The *Ramondias* were also a fine lot, there being in addition to the violet type of *R. pyrenaica*, some forms of this in white and delicate shades of rosy blush, and the very delectable, silver-leaved, *R. Nathaliae*. *Draba*, "*Bees' Yellow*," was shown as a large-flowered late-blooming member of that interesting genus, and one admired some excellent masses of *Cotyledon simplicifolia*, *Wehlenbergias* and *Lewisi* and enjoyed perhaps the best show of *Oxalis enneaphylla*, *O. e. rosea* and *O. adenophylla* that has ever been seen. Though rather early for *Campanulas* there were several notable specimens to be seen, of which *C. stevensii nana* and the new *C. calcicola*, with large blue bells drooping over a curiously mottled and hairy foliage, were among the most striking.

Primulas were a most enchanting lot—a show in themselves. The rare Chinese *P. chrysopa*, *vinciflora* and *rigida* were especially lovely, the last being, despite its misleading name, a dainty, pale lilac species with the elegance and grace of *malacoides*. The great golden candelabras of *P. helodoxa* were everywhere in evidence, as were the fiery orange-scarlets and glowing crimson-*vermilions* of "*Aileen Aroon*," "*Red Hugh*," *Cockburniana* and others. The exquisite *P. sikkimensis* was shown in perfect form, its fragrance and the drooping citron-yellow bells on their mealy stems expressing the very acme of refinement. Another ravishing beauty was *P. nutans*, whose pendant flowers of rich violet together with the stems are all powdered with silvery meal. The glorious *P. Bulleyana* in a warm apricot, the *Beesian* hybrids and a host of other good things, along with several attractive groupings of American *Dodecatheons*, would alone have made the visit to this great show a memorable one.

To many visitors to Chelsea the main objects of interest are the *Azaleas* and *Rhododendrons*, and to a great extent these shrubs may be said to have dominated a large share of the huge tents as well as the out-door gardens. Though an inclement May had left its stain upon some of these there was a truly magnificent display, the enormous mounds and beds of color creating a spectacle of superb

grandeur. Though space would not permit one even to mention individually a tithe of the gorgeous specimens on view in this section, reference must be made to the wonderful Rhododendron Corona, in a full shrimp pink, the blood-red "Lady Constance," "Loder's White" and a new white of the same type, temporarily named "Snowflake." "Bagshot Ruby" and "Brilliant" were still conspicuous among the richer crimsons and that good old variety *R. fastuosum* fl. pl. was well represented in bush and standard form. Kurume Azaleas and other Japanese kinds were well displayed, as were those of the *mollis*, *sinensis* and the late, double-flowered *rustica* set. The well-known "J. C. van Thol," "Anthony Koster" and the newer *multatuli*, with very large trusses in a flaming orange-scarlet, were among the more striking of these impressive throngs of blossom. Japanese Maples and Wistarias, *Ceanothuses* in variety, *Kalmias* and many conifers were conspicuous in the shrub sections, and such Rhododendron species as *cinnabarinum*, *decorum* and *yunnanense* *magnifica* were staged. *Fremontia californica* and the rare *Dipelta floribunda* were both shown full of blossom; the fragrant *Daphne encorium* and the more uncommon *D. Genkwa* were on view, and many who had not seen *Potentilla Farreri* and the newer *Leptospermums* in bloom here saw these attractive shrubs in perfection. On one stand alone there were some two dozen distinct species and varieties of Brooms exhibited, including *Cytisus Dallemorei*, crimson and purple, the lovely *C. sulphureus*, "Ivory," and the many delightful parti-colored forms of the *purpureus* and *andreaeanus* class, many of these being sent out as standards. When I add that in addition to all these (and I have not mentioned a fraction of the exhibits) we had the productions of those growers from S. W. England who are enabled to exhibit from the open air and in full flower such shrubs as *Embothrium coccinea*, *Eucalypti*, *Pittosporums*, *Clianthus*, *Tricuspidarias* and many other tender subjects, one may perhaps imagine the wealth of color and variety which this show afforded.

The greenhouse, or stove, plants comprised an exhibition of vast dimensions in themselves and the same must be said of the Carnations and Pinks, of which there was a ravishing display, especially of the now popular *Allwoodii* class. Against a background of black velvet several tiers of superb Carnations shown by the President, Lord Lambourne, made an impression one will not soon forget. The entries in Clematises from one firm alone covered a space of some five hundred square feet, nearly fifty distinct varieties being staged in faultless condition, and though one hardly expected much in the way of Roses during the last days of May there were some magnificent groupings of Ramblers, Climbers, Baby Polyanthas, Yellow Banksian and others. From one well known Belfast nursery came an exhibit of no less than 10,000 sprays of Sweet Peas in faultless condition, immense in flower and of almost every conceivable tint, these being rivalled, but not eclipsed, by the sheaves of Lupins and *Antirrhinums* which made veritable banks of color from floor to canvas. Oriental Poppies also made a brave show, some of the dwarf and intermediate forms being very delightful, and in *Paeonies* one was impressed by the beauty of extensive arrays of the uncommon *P. officinalis lobata* whose gorgeous crimson single blooms have a large central tuft of golden yellow. The *Eremuri* (Fox Tail Lilies) also created much attention by their majestic spires of blossom, and the exhibition of Irises produced a perfect galaxy of color, among which the newer forms of Spanish Iris, the June-flowering varieties of the Bearded section and the Sibiricans were particularly good.

Among the hardy *Liliums* one noted the now popular *L. regale* probably the most beautiful of all recent introductions. *L. Farreri* was here also, a most chaste little Lily whose pure white reflexed petals are spotted with violet. There were some extensive arrays of the orange-buff, *L. elegans*, "Orange Queen," the very dainty *L. Willmottiae* and the Nankeen Lily (*L. testaceum* or *excelsum*) whose ivory flowers are held in great clusters at the head of six-foot stems. One specialist in *Delphiniums* showed sixty distinct varieties, the splendid colors of the noble spires of bloom, some of which rose to nearly ten feet high, affording a most sumptuous, Oriental effect.

Not less interesting to many were the gardens outside the tents. The day before the show the several acres devoted to these were a quagmire of grimy turf, but by the following noon all this had been transformed as if by magic into smiling gardens of every conceivable style. There were rock gardens, sunken gardens, formal gardens, Spring gardens, blue gardens, water gardens, Dutch and Japanese gardens and many others, all looking much as if they had been here for years instead of a few hours. The rock gardens were particularly good. For the construction of some of these many tons of mountain turf and carefully selected rock had been brought long distances by rail or road, the latter without the mosses or lichens of Nature's adorning suffering so much as an unsightly scratch! These were disposed with consummate cleverness, suitable plants set in their chinks or in the accompanying slopes of sod, whilst rivulets of water and sparkling pools fringed with aquatic plants gave life and movement to the scene. Some of the representations of alpine meadows were also especially attractive, the well-known enthusiast responsible for these having conceived the idea that one might with greater interest and delight have a "lawn" of suitable alpine plants, all set close together, than the more commonplace stretch of grass. The examples shown of these flowerful meadows were certainly fascinating and, even if the idea does not suggest practical usage, there is little doubt but that it will develop as a phase of alpine gardening which may perhaps be truer to Nature than those regiments of stones which so often dominate the rock garden of the unskilled amateur.

IN THE GARDEN AND GREENHOUSE

(Continued from page 172)

down enough to go into the same size pot, if possible. Use a good, strong loam and pot quite firmly. Keep the syringe going on the plants as soon as the operation is finished, and never allow them to get dry, as good root action is essential, before the leaves fall. Examine the roots of any early vines that are clear of fruit. If they have been allowed to go down too deep in the border, they by careful work can be lifted. Uncover them carefully and lift the roots up near the surface of the border working tough, sod loam under them. Spread them out equally, just covering them with some of the broken up turf. We believe the reason that the roots of vines very often go down too deep is that during their growing season, they do not get enough moisture near the surface of the border and feel their way down where it is more damp. Grapes take great quantities of water while they are in active growth, and the surface of the border should always be quite moist. A good coat of Scotch soot scattered on the grape border just before the fruit begins to color will help the coloring. Give the borders plenty of water, until the fruit ripens but discontinue syringing. Some of the varieties, such as "Madersfield Court," as they near ripening need to be kept somewhat drier at the roots or the berries are apt to crack.

The Cultivation of Acacias Under Glass

THOMAS ROLAND

ACACIAS do equally well in pots, tubs, or when planted in beds and can be trained and shaped to any desired form or to fit any and all positions. All thrive under approximately similar conditions of soil, temperature, light and moisture. A sandy or gravelly loam, with some cow manure added, makes a suitable compost for them. They require an abundance of sunshine and fresh air and plenty of water when well established and making new growth, but they cannot endure sour soil or stagnant moisture, and it is essential that the plants, whether growing in beds, pots or tubs, should be carefully and sufficiently drained. I prefer to grow the

Acacia pubescens

plants under glass continually, because they can be better and more easily controlled.

Practically all my plants have been raised from seed or cuttings and grown on under the same general treatment. With one or two exceptions they all root easily from cuttings of half-ripened wood. The latter part of October is usually a good time in which to put in a batch of cuttings because from then on the temperature can be easily controlled. If the cuttings are placed in pots or pans of sandy soil and kept fairly close, in a temperature of about 55 to 60 degrees, they should root in from eight to twelve weeks, depending upon the variety and on the condition of the wood. Cuttings of *Acacia pubescens* may take six months in which to root. Cuttings made of new growth after plants have been cut back may also be put in in the Spring. As it is not, however, easy to control temperatures at that season, I believe more uniform success is likely to result when the cuttings are put in in the Fall.

Perhaps the easiest method of raising stock is from seeds which are freely produced by cultivated plants. Seeds sown in January will produce nice little plants in 2½ or three-inch pots by the end of the first year, after which they grow quite rapidly. It is a good plan before sowing the seed to pour over it water heated to just below the boiling point and allow the seed to remain in the water over night, thus making sure the seeds do not become dry before they are sown. After sowing, the seed should be placed in a temperature of about 60 degrees. As plants raised from seed show much variation, it is desirable when a special variety is needed to propagate it either by cuttings or by grafting.

As soon as our plants have bloomed they are pruned into whatever shape or form is desired. Those requiring potting are attended to at the same time. We find the plants grow as freely in tubs as in pots and that the tubs are much more suitable and better than pots in every way. After pruning and potting, it is best to keep the plants, especially those having been much disturbed at the roots, slightly shaded from bright sun and frequently given a light spraying. They should be placed where strong draughts cannot reach them until they have made new roots. After they become well established they should be given ample space so that they will receive plenty of sunshine and plenty of air.

At no period do Acacias thrive in a moist atmosphere. During the period when they are getting plenty of sun and air it is well to spray them overhead two or three times a day. Several times weekly it is well to give all plants a very hard and thorough syringing. We find this is sufficient to keep the plants free of insects. In the Fall when the plants have set their buds, spraying should only be done on fine days and not too frequently, but it will

Acacia saligna

be found advisable to give all plants a hard syringing at least once a week until Winter.

In case the wood of any plant has become unduly hard because of defective roots, it is advisable to keep it on the least sunny side of the house and perhaps give a slight shade during the brightest portion of the day.

Plants that were not repotted in the Spring may need feeding during the Summer and practically all plants that are well budded and have not made an extra heavy rank growth are, I find, benefitted by a feeding of cow manure water.

It is possible to cut Acacia flowers during every month in the year, but I do not believe it is worth while to attempt to have flowers during June, July, August, and September, because during these hot months they are apt

to lack substance and to be off-color. The varieties named in this paper are at their best from November until April, and on several occasions all of them have been exhibited in full flower and in fresh condition in the month of April. This is easily accomplished by keeping those varieties which would naturally flower during December, January, and February in structures that can be kept at a temperature between 32 and 40 degrees. I might mention here that my entire collection has been exposed, for a period of fifteen hours, to a temperature ranging between 30 and 25 degrees, and so far as I have been able to judge the health of the plants was not affected.

Acacias are at the height of their beauty during the cold and gloomy season when flowering plants are scarce but much in demand. They are quite easy to grow and, as compared with most other plants, not expensive because they thrive in a low temperature. When grown in beds in large glass structures, little labor is required to keep them in a healthy condition. There are many large glass houses in this country admirably suited for the growing and display of Acacias. Could anything be more wonderful and interesting than to see one of these completely filled with Acacia plants in full bloom?

When out of flower the great variety of foliage, both in form and color, makes the Acacias one of the most useful and beautiful of all plants. Some varieties have a blue foliage equalled only in the finest blue spruces. Every shade of green, from the darkest to the palest, is included in the Acacia family. As compared with palms and ferns, which as a general rule are to be found growing in such houses, Acacias would prove easier to manage and more economical and would attract interest and give pleasure to a greater number of persons than the plants usually found in most large conservatories.

Briefly, I would call attention to what I consider the three most valuable species of Acacias now in cultivation. They are *A. pubescens*, *A. Baileyana* and *A. dealbata*. These three species in my judgment are the most beautiful in cultivation and are the most useful and suitable either for cut flowers or as plants for conservatory or house decoration. *Acacia Baileyana* is the earliest of the three to flower and may be had in bloom for Christmas. There are several forms of this species differing distinctly both in form and in date of coming into blossom. This is also true of *A. dealbata*, which flowers a little later. *Acacia pubescens* is the last of the three to come into bloom, and is considered by many persons to be the most beautiful of all Acacias.

GOOD SWEET PEAS WITHOUT DISBUDDING

MUCH has been written in recent years in favor of the Cordon system of growing Sweet Peas, but the continued shortage of suitable help for garden operation and the recent unfavorable seasons, have had a discouraging effect on many of our best growers.

The fact that splendid flowers can be grown without disbudding the vines has often been demonstrated, and while the flowers grown on undisbudded plants lack the substance of stem and bloom that others grown on the Cordon system possess, they also lack the coarseness of the better grown stock.

To cite an instance of this kind a display of Sweet Peas grown naturally was exhibited before one of our Florists' Clubs early last June, and was conceded to be the finest showing of these flowers ever seen by the Florists present at the meeting.

To insure the best success, seeds of the finest varieties should be sown during the Fall, or early in the New Year, the time depending much on the appliances the grower has at his command. Seeds sown during October and

wintered over in a cold frame will give the finest results if the plants are grown sturdily by means of careful ventilation in favorable weather, and given room to develop properly.

Many growers still stick close to the method of sowing and growing on in pots, but better germination can be secured from sowing in flats, and the ultimate results will be as good from plants grown on in flats.

Where pots are used, four or five inch pots should be used to finish off the plants before planting out in Spring; if flats are used, the plants should be transplanted three inches or more apart, and the flats should be four inches deep.

Plants well grown in pots or flats are often furnished with several good stout branches and it does not require a great deal of intelligence as regards horticultural matters to realize that plants of this stature require a good deal of room for future development.

They should be planted not less than a foot apart, and with the best plants, eighteen inches is not too much room to give the plants in the row, and if double rows are planted, which is a good plan to adopt, the rows should be from fifteen to twenty-four inches apart.

Usually the one bone of contention is the matter of supports, good twiggy brush from birch, hazel, elm or dogwood is beyond question the most suitable as regards the comfort of the plants, for if the rows are run north and south, the brush gives a very beneficial shade to the plants during the middle day, and if the brush is neatly arranged, little objection can be made on the appearance of the arrangement. It is a good plan to run two or three wires, drawn very tight, along each side of the brush to help keep the sides in shape and the tops and sides should also be trimmed neatly.

Where suitable brush cannot be secured, or there is an objection, on the part of persons in authority, to the use of brush, other methods must be adopted; poultry wire is no doubt the neatest support, but most gardeners wisely avoid it.

A method we recently adopted which gives pleasing results is to use long cane stakes as for Cordon work, placed six inches apart in the rows, and secured to an overhead wire or wood support, and sloping slightly inward the plants are planted between the stakes, and instead of being disbudded and tied singly to each stake, they are allowed to branch out, and are kept upright by looping and interlacing white string along the stakes. As the plants grow stronger, good strong twine is run loosely along each side and looped in to the stakes. With well grown stock the plants soon fill up the space between the double row and present a pleasing effect, while the length of stem and gracefulness of bloom leave very little to be desired.

Plants grown in this manner will stand considerable feeding in favorable seasons, and are greatly benefitted by a mulch of partly decayed leaves or old manure.

Give a good cultivating weekly during the early part of the Summer until the mulch is applied and this should not be allowed to mat down and choke the soil.

If the grower wishes, a partial disbudding may be made by early thinning the vines, and with some varieties this will give excellent results.—CHARLES ELLIOTT in *American Sweet Pea Bulletin*.

A CORRECTION

THROU GH a typographical error which was overlooked at the time, the number of Darwin tulips used in constructing the John Scheepers, Inc., bulb garden at the last Spring Flower Show was given as twenty-six hundred instead of twenty-six thousand, on page 156 of the June issue.

American Crab Apples

AMONG the small North American trees still imperfectly known to botanists and wood-lovers and scarcely known at all to gardeners are the different species, varieties and hybrids of the Wild Apple. Nine species of these trees are now recognized with several varieties, and two hybrids and their varieties. They have white or pink fragrant flowers which do not open until the leaves are partly or entirely grown, and green or pale yellow fragrant fruit which hangs on slender stems and, with the exception of that of the species from the north-western part of the country, is depressed-globose, usually from an inch to two and a half inches in diameter and

A branch of Bechtel Crab

covered with a waxy secretion. All the species spread into thickets and are excellent plants for the decoration of wood-borders and glades. Some of the species have only been distinguished in recent years, and although the species and many of the varieties are now growing in the Arboretum several of these have not yet flowered; only two or three of these Crab Apples can be found in commercial nurseries.

MALUS GLAUDESCENS, which is named from the pale glaucous color of the under surface of the leaves, is the first of the American species to flower at the Arboretum. It is a shrub usually rather than a tree, not more than fifteen feet high, with stems four or five inches in diameter. The flowers are white or rose color, up to an inch and a half across, and the pale yellow fruit is often from an inch to an inch and a half in diameter. It is common in several western New York counties and ranges to western Pennsylvania, southern Ontario and Ohio, and occurs on the southern Appalachian Mountains to northern Alabama.

MALUS IOENSIS begins to open its flowers several days later than *M. glaucescens*. This is the common Crab Apple of the northern middle western states, and in a number of varieties has a wide range southward through Missouri to western Louisiana and Texas. It is a tree sometimes thirty feet high with a trunk often eighteen inches in diameter, a wide open head of spreading branches and usually incised leaves tomentose on the lower surface, flowers often two inches wide with white or rose-colored petals, and fruit hanging on stout hairy stems, and up to an inch and a half in diameter. The common form of this tree in southern Missouri, Arkansas and eastern Oklahoma (var. *Palmeri*), a small tree with spiny

branches and smaller leaves, is flowering in the Arboretum for the first time this year. A form of this tree with double flowers (var. *plena*), the Bechtel Crab, named for the man who found it several years ago growing in the woods in one of the western states, has opened its pale rose-colored flowers which look like small Roses. When in flower this is one of the popular trees of the Arboretum, judging by the number of persons who want to get close to it. This double-flowered Crab can now be found in many of the large American nurseries, but these nursery trees are often short-lived, probably because the common orchard Apple on which they are usually grafted does not suit them as stock. Persons buying the Bechtel Crab should insist that it be grafted on one of the American Crab Apples, the best for the purpose being the single-flowered type of *M. ioensis*.

MALUS CORONARIA, sometimes called the Garland Tree, is the common eastern species, although it does not approach the coast north of Pennsylvania and Delaware and ranges west to Missouri. It is a beautiful tree sometimes twenty-five feet high with a short trunk, pink flowers rather more than an inch in diameter and depressed globose fruit. From *M. glaucescens* it is distinguished by

Sargent's Crab

the green under surface of the leaves, and from *M. ioensis* by the absence of pubescence on the leaves, fruit stalks and young shoots. The calyx on one variety (var. *dasy-calyx*) not rare in Ohio and Indiana is thickly covered with white matted hairs. A form with long acuminate leaves (var. *elongata*) which sometimes forms dense impenetrable thickets grows in western New York to Ohio, and on the southern Appalachian Mountains from West Virginia to North Carolina. Recently a double-flowered form of *M. coronaria* has been found growing in the woods near Waukegan, Illinois (var. *Charlottæ* or the Charlotte Crab). The flowers are larger and whiter than those of the Bechtel Crab, and there is no reason why the Charlotte Crab should not become as great or a greater garden favorite. It is now growing in the Arboretum but the plants are too young to flower.

(Continued on page 180)

THE SHOOTING STARS

THE genus *Dodecatheon* belongs to the Primula family, and is confined to Western North America, although one or two species are found in North-Eastern Asia by the Behring Straits. They are all hardy herbaceous perennials, with tufts of oblong spatulate leaves of varying shapes and sizes, and scapes bearing umbels of drooping flowers on long pedicels. The petals are long and narrow and reflexed like those of the Cyclamen. They are usually found in moist, shady positions, and are well adapted for the sheltered parts of the rock garden or shady border. The soil they prefer is a loamy one, rich in humus, with plenty of moisture in the growing season. Nearly all the different kinds are easily propagated by division of the crowns after the leaves have ripened off, or the operation may be performed in early Spring.

D. ELLIPTICUM (syn. *D. INTEGRIFOLIUM*).—This pretty little plant is a native of the Rocky Mountains, where it is found in moist, open woods. It has narrow spatulate leaves, quite entire, from which, early in May, are produced scapes one foot or more high, bearing umbels of eight to ten flowers. These vary from rosy purple to pale lilac, and have a white base with a yellow ring.

D. D. M. MEADIAN FOLIUM.—A very distinct plant, one of the largest and strongest growers in the family. It has leaves nearly a foot in length, lanceolate in shape, and tapering to the base, while the scapes often reach a height of two feet in favorable situations. On these the pink or rosy purple flowers are borne in umbels of four to six in late Spring. It is usually found in wet places on the mountains of East Oregon and California.

D. MEADIA.—The most popular member of this genus, easily grown and very free-flowering, is a beautiful plant for the shady border. It produces an abundance of long, broad leaves and numerous scapes up to two feet high, each bearing twenty or more large pendulous reflexed flowers during the month of May. It was one of the earlier kinds to be introduced, having been grown in the year 1709 in the garden of the Bishop of London. It is named in one of the earlier volumes of the *Botanical Magazine*, t. 12, and is named after a Dr. Mead. In its natural habitat it is confined to the country west of Pennsylvania, and usually grows on moist cliffs and drains. There are numerous color forms of this species grown in

gardens, varying from rich rosy purple through all intermediate shades to pure white.

Many of these Dodecatheons make excellent pot plants for use in the alpine house. The roots can be potted up in the Autumn, and the pots should be plunged in an ash-bed in a sheltered position where they can receive attention. During the month of May they will produce their flowers freely and prove a welcome addition to the other plants in bloom at that season.—*The Garden* (British).

AMERICAN CRAB APPLES

(Continued from page 179)

MALUS ANGUSTIFOLIA is the last Crab Apple in the Arboretum to flower. This is a tree sometimes thirty feet tall with a trunk eight or ten inches in diameter, wide-spreading branches, bright pink exceedingly fragrant flowers an inch in diameter, and depressed-globose fruit. From the other species it differs in the only slightly lobed or serrate leaves on the ends of vigorous shoots and in the rounded apex of the leaves on flower-bearing branchlets. *Malus angustifolia* is a southern species which naturally does not grow north of southeastern Virginia and southern Illinois, ranging to northern Florida and western Louisiana. Plants raised here many years ago from seed gathered in northern Florida are perfectly hardy in the Arboretum where they bloom every year late in May and have proved to be handsome and valuable.

MALUS SOULARDII, which is believed to be a natural hybrid between *M. ioensis* and some form of the orchard Apple (*M. pumila*) which, not rare and widely distributed in the middle west, is a tree as it grows in the Arboretum, nearly as broad as it is high with spreading, slightly drooping branches. Last year it was thickly covered with its pale pink fragrant flowers, which, for ten days at least, made it one of the most attractive objects in the Crabapple Collection at the eastern base of Peter's Hill. This year it has bloomed only sparingly. It is a curious fact that *M. Soulardii* flowers in the Arboretum fully two weeks earlier than either of its supposed parents. Several varieties of Soulard's Crab are distinguished by western pomologists. Some of them are in the Arboretum collection, but the "Fluke Apple" is the only one which has flowered here yet. This resembles Soulard's Crab in size and shape, in the color of its abundant flowers, and as an ornamental plant is of equal value.—*Arboretum Bulletin*.

Illustration of the plants in the Crabapple Collection, Peter's Hill, U. S. Dept. of Agriculture. This is one of the interest-
ing specimens collected by the author during the annual excursion to Peter's Hill, August 14, 15, 16, 17.

The Trend of Modern Gardening

WHEN one considers how easily we parted with the carpet bedding style of gardening which prevailed in mid-Victorian days, it comes as somewhat of a surprise to realize that the conventional herbaceous border is still with us and alive and well, writes A. T. Johnson in *The Garden*. This not only because the latter is in many respects no less formal than the old bedded-out arrangement, but also because of the great expense that is entailed in its upkeep. In its orthodox form there is no part of the garden so costly to maintain as a herbaceous border, both in regard to material and labor. Yet, while so many gardens, large and small, are still bearing unmistakable indications that wages and general maintenance remain high, that portion of them which entails the heaviest outlay in time and money is suffered to remain.

There is, however, another point to be considered. I have drawn a parallel between the herbaceous border and the formally laid-out bed which may seem unjustifiable to some; but, as a matter of fact, there are probably not many people, among those who really think about such things, to whom the average border of perennials is the satisfaction that one is led to assume that it is. Indeed, there are symptoms which show that a revolt against the border of this kind has already set in. In not a few gardens it has already ceased to exist, and not only on the score of expense, nor yet because its undoubtedly splendid effect has produced a sense of satiety that is shared by owner and gardener alike. The typical herbaceous border seems likely to follow the carpet-bed because, like the latter, it is wanting in those attributes which are the final and enduring test in all sound gardening, viz., interest in the individual plant rather than the mass; a felicitous treatment of subjects which is the antithesis of formal arrangement; and the impression of permanence, which is one of the greatest lessons we may learn from plants in the wild state and the lack of which is the herbaceous border's most notable failing.

A momentary consideration will reveal the fact that although the bulk of the plants with which the average herbaceous border is made are termed perennials, they are less permanent in one sense than a bed of annuals or "half-hardys." That is to say, the vast majority of them have but a comparatively brief flowering period, which means that gaps in the ranks must be filled up or grown over by others set in with that object in view. Then, most of our hardy perennials do forfeit their claim to what is suggested by that term by demanding frequent lifting, breaking-up and replanting. That they would prove their perennial nature without this attention may be true enough, but in so doing they would quickly deteriorate and eventually lose their characteristic vigor and form. Wherefore, regarded from such points of view, the border of perennials is of anything but a permanent nature. It is much more akin to the shelves of a conservatory than anything else in the garden.

It may be thought that I lay too much stress upon this matter of permanency, or the lack of it; but to anyone who gives the subject a thought it will be manifest that therein lies the essential difference between the gardener who plants for a season a bed or a border, his sole object being to create a certain definite display for a definite period and the man who puts in a plant or a tree which he hopes will become established and remain "a joy for ever," not as a part of a whole, but for its own sake. The one may be fully justified in maintaining that he derives as much pleasure out of his squad of Tulips or carefully screened fancy Pansies as the other gets from his odd patches of

Anemone and Primula interspersed with Rose species and a few other choice shrubs, but the sentiments which inspire each of these respectively are as wide apart as the Poles.

The sort of border which promises to supplant the orthodox type is furnished with individual plants rather than groups. I have no quarrel with the latter where they are desirable, as often they are, but would avoid them where they are to be to the whole what the marble chips are to a piece of mosaic. There are fine old gardens in this country where almost every plant or shrub is an individual and something more. It possesses some special history or interest in addition to its own peculiar beauty or merit, and rather than enthuse over the latest creation of the hybridist's art the owner of such a garden will, as likely as not, point out with keener pride some old variety or species one of whose most cherished attributes is that it is "out of cultivation." We may not all be able to fill our borders with rare treasures, nor would it be desirable to do so. A new Delphinium of merit has as much right to a place in our soil as a bush of Lavender which has been in cultivation with us for nearly four hundred years.

However, to describe the lay-out or the contents of an informal border would be hardly practicable, for each one will be the outcome of the owner's individual taste, a reflection of his individuality, and here, again, you have a clear line of demarcation between the herbaceous and what I have called, in the absence of a better term, the mixed border. The former is, generally speaking, manifestly the result of a carefully worked-out design, possibly the exact replica of one of the map-like plans one sees in nurserymen's catalogues, whereas the latter is as far removed from any indication of such design as is a stretch of moorland or a hedgerow bank. Even though maturity and permanence may be among the most abiding charms of this unconventional border of plants and shrubs, grasses and bulbous things, it is the absence of conscious effort which is, after all, its happiest feature.

RAMBLING REMARKS ON PLANTS

SOME one recently asked us whether any of the Dogwoods bore white berries. Yes, though most species of Dogwoods, for example, *Cornus florida*, *C. canadensis*, *C. mas*, bear red berries; *C. alba*, *C. asperifolia* and *C. paniculata* bear white fruit. Of the other species of *Cornus*, some bear pale blue, others light blue; some lead colored and others deep blue fruit. Judged therefore from the color of its fruits, the Cornel may be regarded as a patriotic shrub, for it represents all the colors of our national flag.

Among the several candidates for the honor of being selected as our national flower, *Kalmia latifolia*, mountain laurel, has been for a long time conspicuous, but as far as we can learn, it has never been given that distinction by a national vote. The chaste beauty of its flowers, varying from deep rose to nearly white, makes this shrub a prime favorite with all who love to gather wild flowers in the "merry month of May." Why has it not then been adopted as our national flower? We cannot answer the question for the masses, but our vote would be against it for one reason; namely, though all of its parts, wood, foliage, flower and seeds are harmless to the touch, when taken internally, they contain elements which place them among the deadliest of our vegetable poisons.

• He who waits to do a great deal of good at once will never do anything.—*Samuel Johnson*.

Foreign Exchange Department

BERBERIS NERVOSA.—This charming little shrub, a native of Western North America, belongs to the Mahonia group, having beautiful pinnate leaves, each often from twelve inches to sixteen inches in length, and of a coppery-purple color. The flowers appear in racemes about eight inches long, and are rich yellow, the unopened buds orange, and very beautiful as they rise from among the coppery leaves. It is a sun lover, and as it rarely exceeds eighteen inches in height forms an excellent subject for placing in the foreground of choice-flowering shrubs, or even on the large rock garden, where its distinct features attract attention at all seasons of the year.—*Gardening Illustrated*.

THE FOAM FLOWER (TIARELLA CORDIFOLIA).—This pretty North American plant is aptly named the Foam Flower, for when growing in bold masses the creamy-white blossoms, when seen in the near distance, seem to suggest the foam or spray of a turbulent sea. It is so generous a bloomer when in a favorable situation that it is quite one of the most valuable

The Foam Flower

of all showy rock plants, especially where striking effects are the desideratum. The foliage, too, is elegant in outline, while the bronze coloration with which it is splashed forms with the flowers one of those pleasing contrasts which Nature so often creates on the same plant. Although this plant was introduced into this country nearly two hundred years ago, it has not become so common in gardens as one might well have expected. Yet it is one of the easiest subjects to manage, and is as hardy as a Primrose. Any ordinary deeply-dug garden soil and a sunny situation are all the plants need. It is quite readily increased by division, and in order to get the best results it is advisable to lift and divide the plants every two or three years. March is a good time to plant. Besides growing the Foam Flower in the rockery it is a good Spring-flowering carpeter for growing among Spring bulbs, or it may be employed as an edging plant to the perennial border.—*Gardening Illustrated*.

ONOCLEA SENSIBILIS.—Among the many good, hardy, garden Ferns native of North America, *Onoclea sensibilis*, the Sensitive Fern, must be considered one of the most desirable. This species is quite hardy and will succeed in any cool soil containing humus, in shade or partial sunshine. It is, however, not very particular, and in most gardens will cover a considerable space, sending out underground rhizomes from which ascend the elegant fronds to a height of about one foot. In the Spring these are a most delicate, almost transparent, green, which eventually changes to a pure, soft emerald green which is an uncommon shade among Ferns. Towards Autumn these fronds become a warm golden-brown before falling.

O. sensibilis belongs to the group known as "Flowering" Ferns, and it makes an admirable companion in the woodland for hardy Cyclamens, Spring bulbs, *Orchis maculata*, *O. foliosa* and other similar subjects.—*Gardeners' Chronicle* (British).

A RARE AND BEAUTIFUL SHRUB.—As long ago as 1780 that beautiful shrub, *Fothergilla major*, was introduced into England. It appears to have been entirely lost sight of by the end of the eighteenth century, both here and in the United States, and was not seen again until a few years ago, when it was re-discovered on the Alleghany Mountains of Virginia and brought once more under cultivation. It is a deciduous shrub, ultimately six feet to eight feet high, erect in its branching, but forming a shapely

bush. The leaves are roundish, three inches to four inches long, dark glossy green above and greyish white beneath.

At the time of flowering the twigs are leafless or only just bursting. The flowers are very curious in having no petals, their beauty being due entirely to the densely clustered stamens, which are pinkish white with yellow anthers and three-quarters of an inch long. The quaint brush-like tufts are composed of numerous flowers, but are smaller than may frequently be seen. They are sometimes cylindrical and two inches long.

The shrub is very hardy, a good grower and easily increased by cuttings. It is difficult to account for its disappearance from gardens one hundred years ago, for they were not then so embarrassed with riches in the way of hardy trees and shrubs as we are today.—*The Garden*.

THE HEUCHERAS.—These lovely hardy plants, the name of which, by the way, is correctly pronounced *Hoikera*, have rapidly won their way to the front rank among dwarf border perennials. Not that they are by any means new, for many species are old inhabitants of our gardens; but the hybridist has been very busy among them, and the introduction of these new forms has given the whole genus a great impetus which has brought the older as well as the newer forms into striking prominence. And, indeed, the plant is ideal from every point of view, the tall, elegantly feathered flower-spikes in contrast with the compact tufts of foliage proving especially happy. Great as the plant is when in flower, a high meed of praise must be accorded to the Autumn and Winter effects of the foliage, for many then take on lovely red and reddish brown hues that persist until the new leaves push out in Spring and cover them.

A very important point in the culture of all species and varieties is frequent division. The plants throw out offsets freely, but as they do so the stems are pushing higher and higher out of the ground, leaving a longer and longer length of bare stem so that the only way is to break them up into single crowns and replant to the lowest leaves. If this is done in September or early Spring, the plants very soon push out an abundance of roots and they flower splendidly the first year. In addition to their use in the rock garden and border, they are ideal plants for edging, though where used in this way as well as in the border, great care must be taken that the soil is well drained.

In addition to their light and graceful habit in the garden, they are really beautiful when the cloud-like sprays are cut and used as table or other decorations. This brings to mind that by growing a few plants in pots and bringing into the cool greenhouse early in the year, an early and especially valuable display may be obtained, for not only do these flower profusely for several weeks, but they can be turned into the open air again as soon as flowering is over and forced regularly every year.—*The Garden*.

THE GARLAND FLOWER (DAPHNE CNEORUM).—This is one of the best of the evergreen *Daphnes*, and, unlike the majority, is of prostrate habit, which renders it valuable for the rock garden and the edges of beds of other shrubs. When this edging happens to run alongside a path the effect of a line of this dwarf shrub in bloom is very fine. The abundance of deliciously fragrant flowers produced by healthy plants is such that scarcely any of the leaves are visible.

The flowers are produced in dense terminal clusters about the middle of April, lasting in beauty all through May, and of a rich rose-pink color. It thrives in a good and well-drained loamy soil, which should not, however, be allowed to become dust dry at any time of the year. It is to be feared that many of the failures one hears of in cultivating this plant on rock gardens are often the result of dryness at the root during the Summer. This shrub enjoys all the sunshine we can give it, but this must be accompanied by a cool root run. It flowers freely and its propagation is of the simplest.—*Gardening Illustrated*.

THE SALPIGLOSSIS.—One of the most charming of our hardy annuals—the *Salpiglossis*—appears to be losing favor as it is rarely seen grown to any extent today. In the average garden one seldom meets with it, and in houses where once it was prized as a pot plant it is a stranger. It is curious that a flower so beautiful in its veinings and so lavish in its output should be neglected. As we all know who grow it, it is a lover of the sun and is never seen to greater advantage out of doors than when located in a south aspect. In the way of culture it needs no more than what is usually accorded to *Petunias*, a light sandy loam suiting it to perfection. It is as a plant for greenhouse and conservatory decoration, however, that one is able to appreciate it the most, and for grouping purposes it is worthy of greater attention.—*The Garden*.

ELIAGNUS ARGENTEA.—This is one of the most striking of the *Oleasters*, with silvery leaves, and the only species native of North America. It grows from six to twelve feet high, and has slender branches, spreading by means of underground suckers, which appear from around its base as in others of this ornamental genus. The narrow, tubular, drooping flowers, silvery outside and yellow within, are deliciously fragrant and pleasing, as they mingle with the silvery-gray leaves in May. At this season a group of

four or five plants is very attractive. —*Gardening illustrated.*

FUNKIAS FOR SHADE.—One of the most cheerful-looking corners of my garden during an unusually dull, cold May was that where Funkias grow. They have been located there many years, and all the trouble they entail is to take them up occasionally for the purpose of division. I do not know of any hardy plant more useful for decorative purposes in a shady position than Funkias. Complaints are sometimes made in gardens where trees overhang that nothing will grow under them, but an exception must be made in respect of these plants, as they love both shade and moisture. Funkias will grow in almost any kind of soil that retains moisture, and are never better served than when planted in the shade. In the open the sun soon mars the color of the yellow and whitish leaves, but given a position under trees or the partial light beneath a pergola their beauty will continue much longer. I regard Funkias as an acquisition in a garden near to town, for they thrive where some plants barely exist, and their hardiness in the most trying winters is well known.—*The Garden.*

SOME DWARF RHODODENDRONS.—For grouping in fairly open woodland, for the margins of shrubberies, the rock garden or mixed border, the Rhododendron family includes a large number of dwarf species and hybrids which are among the most precious shrubs we possess. The majority of them are hardy, and easy to grow to perfection in any lime-free loam in sun or half-shade with some shelter from wind. All that they require, where peat is absent, is a little leaf-mound or really old cow manure at the time of planting and later on as an occasional top-dressing. A cold root-run and one that does not dry out in spring or summer is highly desirable, for the fine, hair-like surface roots are very susceptible to drought. At the same time the drainage must be good, and while the soil is retentive it should be of a loose and friable vegetable nature.

Omitting, owing to the exigencies of space, the mollis, Ghent, rustica and Japanese groups, usually classed as Azaleas, there still remains a wide selection of dwarf species and hybrids of great beauty and interest. Moreover, as such plants as these are almost invariably sent out budded, and as they move better than most things, a display may be confidently expected the first season and this without detriment to the shrub. I need hardly add that many of the Rhododendrons mentioned below are often known as Azaleas.

Usually the earliest to bloom with us, *R. præcox* is also one of the most charming. A hybrid between *RR. ciliatum* and *dauricum* it is a neat-habited evergreen of 3 ft. to 5 ft., with deep green, glossy leaves and terminal trusses of pretty rose-purple flowers. An excellent variety for grouping in woodland or where it can be afforded some shelter from hoar frosts and biting winds, both of which are liable to injure the blossoms.

Another early bloomer is the beautiful Chinese *R. ledifolium*, also an evergreen, with dense, hairy foliage and close, shrubby habit. This fine species, which reminds one of the old *Azalea indica* of greenhouses, and of which it is probably a form, is perfectly hardy here, though a sharp March frost may prove mischievous with the breaking buds. It is, nevertheless, one well worth the risk of occasional disappointments, its milk-white trusses being indescribably lovely. The wise will give *R. ledifolium* a westerly exposure, and, if possible, the protection of some deciduous tree.

Perhaps the most weather-proof of all the smaller Rhododendrons is *R. (Rhodora) canadense*, a deciduous little shrublet and most faithful bloomer. It usually breaks its plum-colored buds in March.—*The Garden.*

Brief Horticultural Jottings

George W. Pittinger, Jr., Asbury Park's Commissioner of Parks, has brought half a dozen redwood seedlings, each a few inches tall, from the Pacific coast and will plant them on the Atlantic coast. The infant trees will be set out in Asbury Park, Red Bank, Freehold and Atlantic Highlands. If the seedlings stand the summer the Commissioner will bring more of them into the State next autumn.

A redwood planted in Burlington county some 25 years ago is still thriving and gives promise of continued healthy growth.

A quarter of a century means little in the life of a redwood. If the tree is alive, say a hundred years from now, there will be ground for confidence that the perils incident to early tree childhood have been averted. Meantime, if this experiment is successful, by 1975 Mr. Pittinger's redwoods ought to be about 25 feet high, for the tree is reported to grow six inches a year. Five hundred years from now they should form a grove of sizable half grown trees. By the year 3000 they will have attained maturity and practically have ceased growing. To reach that stage in redwood development is estimated to require close to eleven centuries which separate 1923 from the year 3000.

Several attempts have been made to cultivate the redwood tree in the Eastern States without establishing conclusively that they can withstand the climate. Sequoias have not been able to stand the winters or the minute fungi, called mildew, which attacked them in Atlantic City regions.—*N. Y. Herald.*

That North Dakota was at one time abundantly covered with a tropical flora is evidenced by the fossils found in rock beds in what is now a treeless plain. That country was once covered with magnificent forests of hardwood timber, with also more or less coniferous growth. Thick beds of lignite (a very soft grade of bituminous coal), indicate that great swamps were once located where now are great plains. Fossils of Fig trees and a Fan Palm with leaves six feet across go to prove that the climate of North Dakota was once as warm as it is now in the south-eastern states along the Atlantic Coast.—*Flower Grower.*

According to reports, the Indian scientist, Sir J. Chandra Bose has demonstrated that plants have, to all intents, hearts which pulsate regularly. By means of a crescograph, which enlarges up to 100 million times, he was able to observe the actual movement of the cells. The problem of how sap rises in plant stems has never before been satisfactorily explained. Capillarity and osmotic pressure is too slow to account for the fact that sap rises in a tree stem more than 100 feet an hour. The Indian wizard has now shown that the cells expand and contract regularly, lifting the water and passing it upward in much the same way as the heart pumps the blood through the arteries of the body. Now is it palpitation that causes some plants to bleed so freely after pruning?—*Exchange.*

The Moss Rose differs from the Cabbage Rose only in the much greater development and branching character of the glands on petals and sepals and the branching of the latter. The Cabbage Rose has been in cultivation for more than 2,000 years, and the earliest record of the Moss Rose is from Carcassonne, in southern France, where it probably originated as a bud-mutation from the Cabbage Rose at least as early as 1696. The mossy character has since arisen independently from two other varieties of the Cabbage Rose.

Thus in 1775 the Unique Rose appeared in a garden in the eastern counties as a tinged-white variety, and in turn gave rise to the "Unique Moss" through a bud-mutation in France about 1843. The Rose de Meaux is a miniature variety of the Cabbage Rose which may date from about 1637. A moss-mutation appeared from this in the west of England in 1801. Both the Moss and Cabbage Rose are sterile, and there is little doubt that all these derivatives arose from the old Cabbage Rose as bud-mutations. The records show that at least seven bud-reversions from the Moss Rose to the Cabbage Rose occurred in the period between 1805 and 1873. In the half-century following 1788 seventeen varieties of the Moss Rose appeared, one of which was single and fertile and extensively used in crossing. Twelve of these bud-mutations are parallel to corresponding earlier variations in the old Cabbage Rose. Bud-mutation is therefore a frequent phenomenon in *Rosa Centifolia* under cultivation, and there is, as the authors suggest, a direct connection between this condition and the sterility. The evidence indicates that the mossy character is in all probability a simple Mendelian dominant. *Journal of the Royal Horticultural Society.*

The United States is one of the very few flower loving nations which does not have a national flower. England has the rose, Scotland the thistle, Holland the tulip, Spain the orange blossoms, Italy the daisy, Greece the olive, Wales the leek, Ireland the shamrock, Australia the wattle-flower, Germany the bachelor's button, India the poppy, Peru the sunflower, and Egypt the lotus. The United States has several candidates for the honor, none of which have at any time been definitely chosen. Japan, another nation of flower lovers, divides the honors between two favorites, the chrysanthemum and the cherry.

Comments from Our Readers

The articles from the foreign magazines which you reprint in the CHRONICLE are interesting to us "old timers" who got our early training abroad and who see English magazines only occasionally. There can be no doubt but these notes are helpful to the gardeners in this country, but just as helpful would be notes from these gardeners, passing their experience along from one to another. Some years ago we had good articles by gardeners which brought up arguments that sometimes became pretty heated. This made them all the more interesting. But the men who wrote these articles belong to the class of the "old timers" and what is the matter with the young gardeners of today? When we old fellows were young, we liked to send along notes, if for no other reason but to see our names in print. Wake up, you young fellows, and show us what you can do.

Massachusetts
A Veteran Gardener

**National Association
Of Gardeners**
Secretary's Office, 286 Fifth Ave., New York

1923 Convention, Pittsburgh, Pa., August 14, 15, 16, 17.

The aims of the association are to elevate the profession of gardening by improving conditions within it.—To cement a closer bondship among all engaged in, and interested in, gardening—to create a greater confidence between gardeners.

Co-operating with the Massachusetts Agricultural College, the association conducts a course in training young men for the profession, whereby they obtain theoretical knowledge as well as practical experience.

OFFICERS 1923

President JOHN BARNET, Sewickley, Pa.	Vice-President R. P. Brydon, Ohio
Secretary M. C. Ebel, New York, N. Y.	Treasurer MONTAGUE FREE, Brooklyn, N. Y.

TRUSTEES (For 1923)—Thomas W. Head, D. L. Mackintosh, Arthur Smith, New Jersey; Robert Cameron, Massachusetts; Andrew L. Dorward, Rhode Island.

DIRECTORS—(To serve until 1924) William Hertrick, California; George H. Pring, Missouri; Robert Weeks, Ohio; Thomas Wilson, New York; Harold Bryant, Connecticut; Harry Cartwright, Michigan; H. Ernest Downer, New York. (To serve until 1925) George Wilson, Illinois; James Stuart, New York; William Kleinheinz, Pennsylvania; Edwin Jenkins, Massachusetts; Carl N. Fohn, Colorado; Joseph Tansey, New York; John Tonkin, Pennsylvania. (To serve until 1926) Alexander Michie, New York; George F. Stewart, Massachusetts; Theodore Wirth, Minnesota; George W. Hess, District of Columbia; R. P. Brydon, Ohio; William C. Rust, Massachusetts; Charles Schroll, Wisconsin.

SUSTAINING MEMBERS

Moore. *W. Virginia*—Mrs. Arthur Lee. *Georgia*—Asa G. Candler, Jr., G. Gumby Jordan. *South Carolina*—Robert S. Mcbane.

LOCAL BRANCHES

NEWPORT, R. I.: Andrew L. Dorward, chairman; Frederic Carter, secretary.
ST. LOUIS, MO.: George H. Pring, chairman; Hugo M. Schaff, secretary.
NASSAU COUNTY, L. I.: James Duthie, Oyster Bay, chairman; John McCulloch, Oyster Bay, secretary.
BOSTON, MASS.: Robert Cameron, Ipswich, chairman; W. N. Craig, Weston, secretary.
WESTERN PENNSYLVANIA: Manus Curran, Sewickley, chairman; Henry Goodland, Sewickley, secretary.
CLEVELAND, O.: R. P. Brydon, chairman; Arthur Brown, Cleveland, secretary.

WESTERN PENNSYLVANIA BRANCH

A meeting of the members of the Western Pennsylvania Branch of the National Association of Gardeners was held in the public school, Sewickley, Tuesday, June 19. Manus Curran, chairman, presiding. The chairman of the convention committees reported progress. William A. Magee, Mayor of the City of Pittsburgh, advised that he will attend the convention to welcome the delegates. The application of A. G. Nash for membership in the national association was endorsed by this branch.

Another meeting of this branch was held at Gen. Forbes Hotel, Pittsburgh, Tuesday, July 3. The chairman of the various convention committees reported in detail, and arrangements are well under way to make a happy and profitable session.

Next meeting will be held at Carnegie Library, Tuesday, July 17.

PRELIMINARY PROGRAM OF THE CONVENTION

Place: Fort Pitt Hotel, Pittsburgh.

Date: August 14, 15, 16, 17.

TUESDAY, AUGUST 14.

- 10:00 A. M. Meeting of the Board of Trustees and Directors.
- 2:30 P. M. Opening of the convention. Manus Curran, temporary chairman. Address of Welcome by William A. Magee, Mayor of Pittsburgh. Response by Robert Weeks of Ohio. President Barnett's Address. Address by a prominent State Official. Response by Thomas W. Head of New Jersey. Greetings by a Member of the Garden Club of America. Response by William N. Craig. Address by E. J. McCallum, representing Pittsburgh Chamber of Commerce.
- 8:00 P. M. Illustrated Lecture in the English Room of the Fort Pitt Hotel on "Hunting Big Game in the Rockies," by A. J. Cogshall, to which the public is invited.

WEDNESDAY, AUGUST 15

- 9:00 A. M. General Business Session, presided over by President Barnett.
- Noon. Recess.
- 2:00 P. M. Afternoon Business Session.
- 7:00 P. M. Annual Banquet, Fort Pitt Hotel.

THURSDAY, AUGUST 16.

- 9:00 A. M. Automobiles leave the Fort Pitt Hotel for tour of East End and Pittsburgh parks, and thence on to Sewickley.
- 8:00 P. M. Social evening at the Fort Pitt Hotel tendered by the Pittsburgh Florists' and Gardeners' Club.

FRIDAY, AUGUST 17

- 9:30 A. M. Leave Fort Pitt Hotel for tour of the city and visit to the H. J. Heinz Company, the home of "57 varieties," where a special luncheon will be served.
- 1:00 P. M. Visit to Westinghouse Electric Company's plant.

(Detailed program will be issued in advance of the convention.)

HOTEL ACCOMMODATIONS

Single room without bath, \$2.50 and \$3; with bath, \$3.50 and \$4.
 Double room without bath, \$4 and \$5; with bath, \$5 and \$6.

Members attending convention should write in advance direct to the Fort Pitt Hotel to reserve accommodations.

CLEVELAND BRANCH

Meeting of the Cleveland Branch of the National Association was held at Alhambra Restaurant, June 18, Mr. Brydon presiding. All members were urged to explain to their employers the aims of the National Association and that it would be to the employers' interests to become sustaining members.

After general discussion of various subjects, including the coming Pittsburgh convention, the meeting was declared very satisfactory. Next meeting at the Alhambra Restaurant, Euclid Ave. and 105th St. on Monday, August 6, dinner at 7 P. M.
 A. BROWN, Secy.

NORTH SHORE, ILL. BRANCH

At a meeting held at Lake Forest, Ill., on July 6, the following members organized a local branch: James A. Wilson, William Griffith, Frank Kuehne, Robert Kuehne, Marc Twinney, Walter Sims, William Stewart, Thomas Blair, William Michie, John R. Clarke. Mr. Wilson was elected chairman and John R. Clarke, secretary. The secretary was instructed to communicate with the national secretary to secure information which will give the branch a good start. The prospects are bright for an active branch as there are many gardeners in the neighborhood who will be likely to join.
 JOHN R. CLARKE, Secy.

NEW MEMBERS

Active: John Nichol, Yorkes, N. Y.; Richard Powers, New York, N. Y.; Joseph Bradley, Deal, N. J.; William MacKenzie, Elberon, N. J.; James Clark, Newton, Mass.; F. Lloyd, Locust Valley, L. I.; Robert Hughes, Glen Cove, L. I.; Frank E. Sladen, Cohasset, Mass.; A. G. Nash, Dawson, Pa.; John Rutherford, Greenwich, Conn.; John McLaffie, Cleveland, Ohio; Charles Wilkinson, Elberon, N. J.; Frank G. Black, Phoebus, Va.; Duncan Munro, Brooklyn, N. Y.; Robert Gardner, Gibsonia, Pa.; Fred Boepple, Deal, N. J. Associate: Thomas Knight, Rutherford, N. J.

AMONG THE GARDENERS

James Warr, for a number of years gardener on the C. S. Eaton estate at Marblehead, Mass., and more recently gardener to Mrs. Ben Ali Haggin, Tannersville, N. Y., has accepted the position of gardener to T. A. Tedcastle, "Hillcrest," Milton, Mass.

Alec Arthur secured the position of gardener to Fletcher Brown, Wilmington, Delaware.

Donald Crighton, for the past three years gardener under Robert Cameron, superintendent of Castle Hill Farm, Ipswich, Mass., has accepted the position of gardener on the estate of Mrs. Paul Moore, Convent, N. J.

John R. Ness, formerly with Paul D. Cravath, has been appointed superintendent of the Garden City at Shawsheen, near Lawrence, Mass., belonging to the American Woolen Co. He commenced his duties there last month.

LOCAL SOCIETIES

NASSAU CO. HORT. SOCIETY

This society held its monthly meeting in Pembroke Hall on Wednesday, June 13. President James Gladstone occupied the chair. Mr. Thomas Leeming was elected to honorary membership and one petition for active membership was received. Mrs. Harold I. Pratt attended this meeting and gave a very interesting talk on how to improve our exhibitions and increase our membership. John F. Johnstone, James Kelly and Arthur Cook were appointed to work with the North Shore Garden Club. Exhibits for July meeting will be 12 mixed Gladioli, 3 heads of Cabbage and 25 String Beans.

ARTHUR COOK, Cor. Secy.

WESTCHESTER AND FAIRFIELD HORT. SOCIETY

The regular monthly meeting was held in Greenwich, Conn., June 12. The meeting was well attended. Members from the Tarrytown and the Stamford societies were guests of the evening.

The following were chosen a committee for the September flower show: Edwin Beckett, W. P. Robertson, W. J. Sealey, William Smith, James Stuart, James Tough, and John Wilson. After considerable discussion it was decided to hold a basket outing this year instead of the usual shore dinner. A committee was chosen to meet the Stamford and Tarrytown outing committees and decide upon a place to hold a joint outing.

A schedule of classes, other than the usual A. N. Pierson and J. H. Troy competition was held at this meeting. The classes and winners were as follows:

- Class 1—No entries
 Class 2—Roses, Hybrid teas, 6 varieties, 3 of each. First, Edwin Beckett; 2nd, George Hewitt.
 Class 3—Vase of Iris, 3 varieties, 6 of each. First, T. J. Bulpitt; 2nd, Nick Vasloff.
 Class 4—Peonies. First, W. D. Robertson; 2nd, T. J. Bulpitt.
 Class 5—Sweet Peas, 25 Sprays. First, John Andrews.
 Class 6—Herbaceous perennials, 6 vases, 6 species. First, James Tough; 2nd, James Linane.
 Class 7—Vase of outdoor flowers, arranged for effect. First, Andrew Kneuker; 2nd, Peter McCabe.
 Class 8—Six varieties of vegetables. First, James Tough; 2nd, James Linane.
 Class 9—Lettuce, 3 heads. First, James Linane; 2nd, James Tough.
 Class 10—Cauliflower, 3 heads with foliage. First, H. F. Bulpitt; 2nd, James Tough.
 Class 11—Strawberries, 2 quarts. First, James Tough; 2nd, John Wilson.

Range of V-Bar Greenhouses Built for Mr. Emil Winters, Pittsburgh, Pa.

"One Good Job Begets Another"

To the National Association of Gardeners:—Greetings

While at the Annual Convention of the Association you will have a good opportunity to see for yourself why so many of the best gardeners in the country recommend Lutton V-Bar Greenhouses.

In Pittsburgh and Sewickley we have built V-Bar Greenhouses for the following:

Mrs. J. D. Lyons, Sewickley, Pa., John Barnet, Gardener.
 Mr. H. L. Mason, Sewickley, Pa., James Murphy, Gardener.
 Mr. E. A. Woods, Sewickley, Pa., Henry Gibson, Gardener.
 Col. J. M. Schoonmaker, Sewickley, Pa., John Carman, Gardener.
 Mr. B. F. Jones, Jr., Sewickley, Pa., H. Baumgartel, Gardener.
 Mr. W. S. Mitchell, Pittsburgh, Pa., Robert Ladner, Gardener.
 Mr. Emil Winter, Pittsburgh, Pa., Otto Rost, Gardener.
 Mr. E. M. Herr, Pittsburgh, Pa., Charles Gittings, Gardener.
 Mr. Geo. Mesta, Pittsburgh, Pa., Augustus Weber, Gardener.

The Lutton V-Bar type of greenhouse construction is the most durable, lightest, strongest, most sanitary and efficient type of greenhouse built. There is a complete galvanized iron and steel framework and the glass does not touch the metal but rests in a cypress cushion and all condensation is properly taken care of.

Ask the Man Who Has One

WM. H. LUTTON COMPANY

260 Kearney Ave.,

Jersey City, N. J.

In the monthly competition James Wilson 1st for a vase of Gladiolus, Alice Tiplady; Edwin Beckett, 2nd for vase of Lillium Speciosum; W. D. Robertson, 3rd for a Cattleya Gaskelliana. Other exhibits included six pots of Gloxinias, W. J. Sealey; Iris, H. F. Bulpitt; Roses, Chas. Adcock; Trachelium, Alex Smith. In vegetables, H. F. Bulpitt received 1st and James Linane, 2nd.

A. KNEUKER, Cor. Secy.

DELPHINIUMS

Gardening is an art which has been the study and recreation of men for all ages. Its literature is exceedingly voluminous. But although we have this great body of literature and historical records of the art there must forever be beginners. We would

suggest that the beginner in gardening start with well known favorites and when these have become well established, finer subjects, or perhaps those which require more care may be added. We are indebted to many amateurs for valuable plant introductions from other lands and indeed much of the best work in gardening and the development of plants has been done by the man or the woman whose business has lain in an entirely different direction than that of horticulture. Most flowers, it will be found, deserve especial care and treatment. There are many genera or families that offer opportunity for study when taken up in detail. There are several popular plants such as Dahlias, Peonies, Chrysanthemums, Roses, etc., but one that deserves mention is the Delphinium.

The Delphinium is coming into popularity. There are in cultivation many species, both annual and perennial, but the most important are the tall hybrid perennials. They are valuable for their wonderful range of color and great variety in height. Colors range from almost scarlet to pure white, from the palest lavender up through every shade of blue to deep indigo. And for the variety and size of their individual blooms, some of which are single, some semi-double, and some perfectly double, set on spikes from one to six feet in height. There are about a dozen species in cultivation. The combinations in which they can be placed are numerous. They may be used in the mixed border, in masses or groups, in one or several colors, or associated with flowering plants or shrubs. Planted against a mass of Evergreens they form a beautiful picture. Delphiniums can be made to bloom for several months by continually cutting off the spikes after they have done flowering. If the centre spike is removed the side shoots will flower, and by thus cutting off the old flowers before they can form the base they keep up a succession of bloom. Another plan is to let the shoots remain intact until all have done flowering, and then to cut the entire plant to the ground, when in about three weeks there will be fresh bloom. In this case to keep the plants from becoming exhausted they must have a heavy dressing of manure. A good way to Winter large clumps of Delphiniums is to put some coal ashes over the crown of the plants after cold weather has set in. This plan will eliminate the decay so often found in the Spring.—*William Graham.*

PLATYCODON OR CHINESE BELL-FLOWER

This is one of my best perennial flowers, as it blooms constantly from end of June to late in September. This is also known as Balloon flower, as the flower before completely opening up resembles a balloon. The blue or white star, bell-shaped flowers appear in numerous loose racemes. One or two-year roots will bloom the first season set out, and after that appear annually. In Fall when the stalks become dry they should be cut off four or six inches above the ground. Do not pull the stalks, as the buds for next year's blooms are at the bottom of the stalks near the root. Will make a dense branching bush about two feet high the second year, which should be tied to a stake.—*Wisconsin Horticulture.*

COMBATING FRUIT TREE BORERS

The best and surest remedy for borers after they have gotten into the trees is the old and much used way of digging or cutting them out. An experienced fruit man can readily locate borers by the oozing of sap or the small amounts of sawdust coming from tiny holes in the bark leading from their burrows. With the aid of a sharp knife or chisel these pests can be reached and dug out, or a wire may be pushed into the burrow and the grub impaled. Great care must be used with this method, or the trees will be injured more than the borer. Trees should be thoroughly examined in the Spring, not later than May, for this pest. At this time they are easily located by the sawdust-like castings. Others which are just transforming into beetles may be also destroyed. Continue the use of the knife during the Summer whenever a borer can be located and go over the trees thoroughly in Autumn also. You can get the younger borers which are working beneath the bark at this time.

USE SUNOCO SPRAYING OIL FOR Box Bush Leaf Miner

Box bushes, to prevent damage from this pest, should be treated in early May, as the adult flies begin to emerge from the foliage. Circulars on this pest and method of treatment mailed free upon application. Ninety per cent control possible.

1 gal. can, \$1.00; 5 gal. can, \$4.00; 15 gal., \$10.50.

One of the best preventive measures is clean culture. Rank growths of weeds, water sprouts and other vegetation harbor and encourage borers and such vegetation should not be allowed to accumulate at the base of fruit trees.—*Fruit, Garden & Home.*

PROPAGATING RAMBLER ROSES

It is very easy to propagate Rambler Roses by cuttings of ripe wood in July. We usually take the tip of a branch which has flowered, as that ripens earlier, cutting it about eight or ten inches long, the lower end being just below a bud. Trim off some of the foliage if there is much of it, and set in mellow ground to a depth which leaves about two buds above the ground, then invert a fruit jar or other wide-mouthed bottle over the cutting, after watering it. It is preferable to place the cutting in a rather sheltered locality, and our own practice is to put them, as a rule, under or around the parent bush. Very often we do not even cover with a jar, but it is more certain to do this, especially if the season turns very dry after the cutting is set. Leave the cuttings untouched until the next Spring, when a high percentage of them will be rooted, and may be set like nursery plants. If you have a favorable locality in a Rose bed where you can water the cuttings and give them clean cultivation, you would probably root them very well without covering with a glass jar, but it is an added protection.

These Roses are also very easily propagated by layers, bending down a matured shoot in Spring, with a slight cutting or heel in the bark on the under side, then putting earth over the place where they are fastened in the ground. In many cases such layers will have a great bunch of roots the following season, and may then be cut from the main plant and set wherever desired.— (*Rural New Yorker.*)

Daily you plant seeds. What kind are you planting, careful or careless seeds? Seeds of cheer, hope, joy, tolerance, humility, or seeds of selfishness, anxiety, self-pity, scorn, envy, bitterness, and the like? Do you spread cheer, or are you a long-faced pessimist? Are you hopeful, or do you express anxiety, fear, and doubt? Have you tolerance for the views of others, or are you impatient and scornful? Does a brother's deserved success cause you envy, or do you rejoice with him? Do you magnify the so-called faults of your neighbors or minimize their weaknesses? Are you pleasant and agreeable in company, but heavy, dull, or serious at home? These are a few of the seedlings you are planting every day. Cultivate the soil vigorously; uproot the unruly, unlovely weeds which hinder your progress. Think about your mental garden. It is your richest possession, your dearest treasure, that which reflects you as you really are. The way you tend it, feed it, nourish it, clothe it, proves what you think of it and desire it to be. Make a fresh start this day to mirror to the world the cultivation you give your garden. The happiness, peace of mind, growth, and success which are your divine inheritance cannot then escape you.— *Daily Times, Visalia Calif.*

ROSE WORLD AGOG WITH ANTICIPATION

THE rose-world is just now agog with anticipations of new red roses, and there is a rose of recent introduction which may be employed to impart its marvelous coloring to hybrids that shall satisfy our tastes for something other than we've got: It is *R. Moyesii*, a single of the climbing habit, introduced from China in 1904, but said to be of such a curiously intense coloration that hybridists are probably even now seeking to prepare us new wonders from it. If the solidity of coloring which distinguishes *R. Moyesii* can be imparted to the hybrid tea type we shall be blessed with something wonderful in red roses, for *Moyesii* is described as perfectly wonderful enough in itself.

It is an extraordinary fact that notwithstanding the eminence of British rose-growers there is, as yet (though the subject is now under discussion between the authoritative bodies there, no definite rose garden which establishes the hall mark of rose-growing for this great cult. America does this better, for Cornell and Yale universities have established rose-gardens with more than the garden as their viewpoint. France has paid her tribute to the rose by the great rosery at Bagatelle. But it has remained for that great rosarian of France, M. Jules Gravereaux, to design a scientific memorial to the rose: in his tremendous collection of some eight thousand varieties he has set out a vista of Rose History. In this retrospective collection there is traced the history, distribution, and development of the rose in a manner which we believe is without equal elsewhere in the world. This is his modest description of it, but consider what a labor and achievement it represents:

"Here is exhibited a series of characteristic types showing the different aspects of the Rose throughout the ages. On one hand are the wild Roses, classified according to a new standpoint, the probable order of their dispersal over

the earth and according to their general physiognomy.

"Firstly, the most imperfect Roses, which must have been the earliest comers. *Rosa berberifolia* with simple leaves, *R. maracandica*, *R. minutifolia*, *R. microphylla*, etc.; then the Roses with prickles, the epidermis covered with hairs and fine acicules, whose habitats are the high altitudes, *R. Webbiana*, *R. sericea*, *R. acicularis*, etc.; then the Roses without prickles of the lower mountains, *R. alpina*, *R. ferruginea*, *R. cinnamomea*, etc.; the Roses of the forests, needle-prickled, *R. canina*, *R. rubiginosa*, *R. oxyodon*, etc.; then the Roses of the warm climates with shiny foliage, as *R. bracteata*, *R. lævigata*, etc.; and lastly, the roses with perfect organs, probably the most recent, *R. indica*, *R. moschata*, *R. multiflora*, etc.

"Facing these wild roses are the cultivated ones which we can, starting from the Greek civilization, know with some certainty. Beginning with the Roses of Theophrastus, the centifolia and the Rose of Mount Pangæus and concluding with the most recent races, *Wichuraiana* and *Pernetiana*, about fifty types show the successive stages of our garden Roses.

"The history of these Roses comprises three periods—viz.: from the earlier times to the end of the eighteenth century is the region of the centifolia and Provins Roses; at the end of the eighteenth century was the period of the importation into Europe of Roses altogether different, those which came from the Far East; and finally in the nineteenth century appeared the new races, the results of crossing the latter with our ancient varieties."

In this grand rose-growing country we ought to attempt a similar enterprise—not in plagiarism, but to submit to a scientific basis our tribute to the rose, *Queen among Flowers*, whom we, by merely "growing" have relegated to the position of handmaid.—*South African Gardening and Country Life*.

The Tribute of James MacDonald to Davey Tree Surgery

Larrytown, New York.

The Davey Tree Expert Co., Kent, Ohio.

Gentlemen:

It gives me great pleasure to compliment you at this time on the splendid work that has been done on the trees under my charge during the past few years.

There is no denying the fact that the money spent in fixing the cavities, bracing the weak limbs and trimming the trees has been a great and worthy investment.

I may say that every cavity, without exception has healed over perfectly and has not been affected by climatic conditions.

I have had several tree experts and superintendents visit me here and all declare the work is wonderful.

I will have no hesitation in recommending the work of the Davey Tree experts to any person who has any love for the noble and beautiful trees on their estates. I think it is a crime to see how some of the noble landmarks of the country have been allowed to decay when they could have been preserved for hundreds of years more by such men as you employ who have the interest at heart and know how to preserve those old trees for the benefit of the future generation. Sincerely yours,

JAMES MACDONALD.

It is a well known fact that the preservation of trees and the care of their needs highly skilled assistance. Many, like Mr. MacDonald, protect their trees by employing the Davey Tree Expert Co. for the preservation of their trees.

Things and Thoughts of the Garden

WILLIAM N. CRAIG

NOT many appreciate the potential dangers to gardens from the European corn borer. Not only does it attack and almost entirely ruin corn, especially sweet corn, and numerous other vegetables, but a great many flowers are badly attacked; the varieties which are banned from shipment from the infected areas unless inspected include zinnias, asters, chrysanthemums, cosmos, dahlias, gladioli and hollyhocks which by no means complete the list of plants attacked. There are many other annuals and perennials, and most serious of all, roses. It was felt for some time that roses from their woody nature might prove immune, but such is not the case, as they are being badly attacked both outdoors and under glass. One commercial grower told me a few days ago that his loss under glass this season was at least \$1,500. The moths fly into the houses, deposit their eggs on the young shoots and the little borers when hatched start to tunnel down the shoots completely destroying them. It seems not improbable that if this serious pest continues to spread, growers of both roses and chrysanthemums in the infected areas, which are being constantly extended, will be obliged to protect all ventilators and doorways to prevent the moths from entering. The bulk of readers of the GARDENERS' CHRONICLE of America will fortunately know nothing of the deadly damage now being done over a wide area in Massachusetts, and a number of other states, and it is sincerely to be hoped that parasites may be propagated in sufficient numbers very soon to control the pest. To any who may find any of these destructive pests I would counsel the cutting off and burning of all attacked shoots and in Fall the gathering together and burning of all dry weeds and other forms of debris. Many weeds as well as cultivated plants are attacked and cleanliness added to watchfulness are the best methods of prevention and protection.

* * *

I wonder if any readers of the CHRONICLE have succeeded in flowering the stately and beautiful *Lilium giganteum*? This is the most noble of all hardy lilies and is not to be confounded with the "giganteum" of florists which is merely a form of the well-known Easter lily *L. longiflorum*. A few weeks ago I had the pleasure of seeing a very nice spike ten feet in height within five miles of the Boston State House. This was in an ideal location in a well secluded piece of woodland, protected from cold winds. The spike carried ten flowers, which are white in color, tinged a little with green outside and with purple inside. *L. giganteum* is a native of the Himalayas and is usually classed as somewhat delicate, but stands rigorous Winters if well mulched. It succeeds well in the south

of England, but I have seen splendid spikes in the English lake district and on the island of Arran on the west coast of Scotland. Sir Herbert Maxwell of Monrieth in Wigtownshire grows large colonies of this noble lily and flowers it finely. It takes five or six years to grow a bulb to flowering size from seed. After blooming the bulb is of no further value, but it leaves a number of offsets which can be transplanted and grown along. The foliage is larger and more handsome than that of any other lily.

* * *

Speaking of *Lilium*s, I wonder if it is generally known that *L. longiflorum* Formosum makes an excellent garden lily? About the middle of July I saw some excellent spikes three feet or more in height in a garden on the South Shore of Massachusetts. The head gardener informed me that plants which had been flowered under glass were cut back and planted outdoors, that they had withstood two Winters without protection and had flowered splendidly. I have planted out the giganteum form of *longiflorum* in late Fall and these have wintered and flowered well for one season, sparsely a second season and then disappeared. This is the way *L. auratum* acts with most of growers, but in a rhododendron bed with a generous mulch of leaves which are never removed and where the plants do not overshadow it too much, this latter variety and our handsome native variety *L. superbum* have seemed very much at home.

* * *

The bulbs of that immaculate garden lily *L. candidum*, known as the St. Joseph's, Madonna, Annunciation and Ascension lily, are the earliest to arrive in this country, and the sooner they are planted the better, for they start to root and make a rosette of leaves in August and September. This is much the oldest of all lilies in cultivation, being introduced to England from southern Europe as long ago as 1596. Many amateurs fail to grow it successfully. It will often be seen in old gardens growing and flowering with a reckless abandon, while in many pretentious ones it seems very unhappy and is badly diseased. Like all lilies it dislikes fresh manure, but a mulch of old manure proves very beneficial in the growing season. While it will grow and flower very well in full sunshine, I have had better success with it in partial shade, especially where broken somewhat from the morning sun. Wherever planted it should not be too close to other plants, and it is especially necessary now to give the plants full light when the new leaves are pushing up. While the bulk of lilies need deep planting, *L. candidum* should only be covered four inches. Rolling the bulbs in sulphur before

planting has helped to keep plants clear of disease, also tipping them a little sideways.

* * *

The common "Tiger lily," *L. tigrinum*, while a native of China, has been in cultivation for one hundred and twenty years and is seen quite often growing along roadsides. In New England I have seen abandoned farms where lilacs and this lily bore mute testimony that at one time flower lovers dwelt there, but had given up the struggle when the great western wheatlands poured in food far cheaper than they could raise it, when their children lured by the cities' call left, and when the old folks discouraged gave up the struggle and left their homesteads for Nature to reassert itself on them. The showy tiger lily, while too gaudy for admission to the average garden where colors are carefully culled, and where pink, white and blue are about the only ones tolerated, have their place in the perennial border, and wild garden. No other lily will so soon naturalize itself; it propagates readily from seeds and from the bulbils so abundantly produced in the axils of the leaves.

* * *

A very fine garden lily which flowered early in July is *Hansonii*, commonly known as the "Golden Turks'-Cap Lily." This is one of the most dependable lilies in cultivation and succeeds specially well in full sunshine and with *tigrinum* thrives extremely well in a heavy soil. Some of the best I have seen were growing in a stiff, retentive clayey loam. For cutting this is one of our very best lilies for the garden, and if given a place where it will not be overshadowed by other plants will grow, flower, and increase most satisfactorily. The flowers are produced loosely on the stalks, are slightly fragrant and spotted with purplish brown, the anthers are of an orange-red color.

* * *

Very vigorous and thoroughly dependable as a garden lily is *L. Henryi*, sometimes called the "yellow speciosum." It is, however, a far more persistent variety than *speciosum*, and not infrequently attains a height of seven to eight feet. It is furthermore of an entirely distinct habit of growth from *speciosum*, and retains its foliage far better. It is no uncommon thing to see spikes carrying twenty-five to fifty flowers and as many as one hundred and twenty have been produced on a specially robust stalk. Disease which attacks so many lilies appears to but rarely touch *L. Henryi*. Planted a foot deep it grows best, and it is well to lift and replant clumps once in three or four years. There are many forms of *L. speciosum*, and this is a deservedly popular lily in the garden; as well as for culture in pots. Its colors fit into garden schemes where special color effects are desired, better than *Henryi*, but the latter is much more disease proof and persistent. Perhaps when we are driven by the Federal Horticultural Board to raise our own lilies we may from home seedlings get rid of much of the disease which seems peculiar to imported lilies.

* * *

Some twenty years ago Farquhars' of Boston introduced *L. Philippinense*. I well remember the award of a gold medal to them for it by the Massachusetts Horticultural Society. I grew this in pans for two or three years, several bulb flowering well in six or seven-inch receptacles. The plants did not exceed eighteen inches in height at the maximum, and usually only one of the large, trumpet shaped and fragrant flowers was produced. This appears to be a very capricious and uncertain lily and I have not seen it for years. It appears in one or two English catalogs, and is occasionally exhibited over there, but it is strange that it should so completely disappear in America. It would be interesting to know if anyone on this side still has this lily. It is, of course, only adapted

for pot culture in our cold states, but there should be considerable areas in the warmer sections of the country well suited to its culture. Its waxy, white flowers are delightfully fragrant, and the flower stalks are slender and graceful. I have not seen more than two flowers on a stem.

* * *

There are more forms of *L. elegans* than of almost all other hardy lilies combined, and the beginner in lily culture will not go far astray in trying one or more of them. They come in quite a wide range of colors and the various forms all appear to have a greater freedom from disease than the bulk of the species. In one list I have before me twenty-seven distinct forms of *L. elegans* are cataloged and there are many others. We do not see much of that exquisite variety *L. testaceum*, which is sometimes listed as *Isabellinum* and *Excelsum*. This is not found anywhere in a wild state and is believed to be a garden hybrid between *candidum* and *Chalcedonicum*, the scarlet "Turks' Cap lily." The bulbs are similar in appearance to those of *candidum*. It derives the name "Nankeen Lily" from its nankeen yellow colored flowers. Vigorous spikes of this lily will attain a height of six feet and carry a dozen each of the deliciously fragrant flowers. Still another lily we do not see much of is *L. Browni* which flowers here early in August usually carrying but one of its large trumpet shaped flowers to a stem, although I have had four and five on vigorous stalks. The flowers are as much as eight inches in length. Within they are creamy white in color, suffused with yellow; without they are heavily tinged with purple. This fine lily needs supporting when in flower as the large and fragrant flowers are very heavy. While coming from Western China and considered a very hardy species, it is a fact that, unless on very well drained lands, the bulbs are liable to decay in Winter.

* * *

Of all the many garden lilies, I doubt if any is so altogether dependable and satisfactory as the *Regal Lily*, *L. regale*. I have never yet seen disease on this variety. I have seen as many as twenty-six flowers on a stem in an open field in the near vicinity of Boston, and noted several this season carrying twenty each. It is remarkable that the stalks in spite of their apparent slenderness will hold the flowers up well. I have seen a block of three acres growing in New England on an exposed hillside, which needed no Winter protection, and which was a glorious sight when in flower. No supports whatever were needed to hold the flower stalks erect. They have forsooth a grace lacking in many lilies.

* * *

A very pretty hardy annual, carrying pale blue flowers and not exceeding a foot in height, is *Asperula azurea scitosa*. This annual will flower in June from an early sowing and successive sowings may be made as in the case of sweet alyssum. This *Asperula* is effective as a bordering plant and is also good for massing; the color could hardly be displeasing to anyone. Too few amateurs grow the *Browallias*, and while this is really a perennial plant, it is generally treated as an annual. *B. speciosa major* is the best variety and the large bright blue flowers, with a white throat, are very abundantly produced for months. *B. elata* has much smaller flowers than *B. speciosa major*, but is an excellent bedding plant; both deep blue and pure white varieties are readily raised from seeds. *B. speciosa major* makes a very fine pot plant and it is also splendid in baskets.

* * *

Speaking of basket plants, it is surprising that more are not grown. *Browallias* are but one of many varieties available for growing in this way. *Fuchsias*, like *Trailing Queen* and others, make grand basket subjects, and if grown in partial shade will flower from June until Octo-

(Continued on page 204)

In the Garden and in the Greenhouse

GEORGE F. STEWART

IN THE GARDEN

THIS portion of the year, late August and early September, was the last month of the year with the ancients. They gave it the name *Elool*, a word which comes from a root in the Hebrew language meaning "to lament or mourn." This being the driest month of the year in Judea, vegetation became all dried, and burned up, causing a scarcity of food for cattle and much distress. A feeling of sadness sometimes comes over us as we go into September with occasionally an early frost, cutting short the fall flowering season in the garden.

Everything in the garden is reaching a climax. Many fruits and flowers have gone by, and others are fast approaching the ripening period. The last of the season's flowers will be in their full glory. The beautiful *Anemone japonica* is at its best generally when an early frost comes and destroys it. The late flowering *Aconitums* we also have at this season, very welcome indeed when yellow colors seem to predominate. *Helianthus* in variety stand out boldly in the borders, *Boltonias*, late flowering *Phlox*, *Lilium speciosum rubrum*, *Henryii*, and some of the earlier *chrysanthemums* keep them company. A touch of pink would be very helpful in the borders at this season. We have tried pink *Dahlias* but the least bit of early frost generally blackens them if they are at all exposed to the morning sun. Late flowering *Cosmos* are very often cut down with frost before they flower and we have to resort to pot growing to get any flowers from them.

Perennial seeds may be sown for next year's garden. The borders will require constant attention to make them look well. Staking, hoeing and watering must be attended to and all dead flowers removed.

Lilies for next year's garden may be planted as soon as received. Plant at least ten inches deep. It is a pity that growers of lilies for commercial purposes do not grow their bulbs entirely from seed. If they did so, I believe we should be very little bothered with diseased bulbs as small lots that we have grown seem to be entirely free from disease.

The *Dahlias* will now be flowering and if large flowers are desired, disbudding will have to be resorted to; they should also be given plenty of water at this stage, and strict attention paid to staking. A little stimulation with plant food will help their flowering.

Gladioli should have been planted deep enough to do without staking, though it is safest to examine them to see if they need any support before the weight of the spike tips them over.

Give the rose beds plenty of food and water; remove all faded flowers.

This is a good time to look over the peonies to see if the clumps are growing too large or if any variety should be discarded to give place to something better. We examined quite a few seedlings while judging at the Massachusetts Horticultural Society this Summer, and truly they are getting like several other things; the variations from known varieties are very few. Indeed, it would take a connoisseur to detect the difference of many of them.

Seeds of *pansies*, English daisies, forget-me-nots, blue Butterfly *Delphiniums* should be sown about the first of August. *Delphinium Blue Butterfly* is classed as an annual in some catalogs, but it is a perennial. We have had a plantation in the same place for three years and this year it has been a mass of flowers. It is one of the finest plants for cut-flowers we have had, and keeps flowering over quite a long period.

Any planting or changing of evergreens may be done in early September. A deep well-pulverized soil is what they delight to grow in, but great care should be taken that they do not suffer for lack of water. But on the other hand, do not over-water. The new positions should be all in readiness before the plants are dug so that the roots will not be long exposed to the air. Plant them firmly and give a clean cut to any of the strong roots that have been broken in the operation. Conifers as a rule seem to make new roots in September as soon as the ground becomes moist after the dry weather in Summer.

The celery will now be growing fast and every encouragement should be given to it by hoeing often, to keep it free from weeds and to keep the surface of the ground open and loose. An occasional application of fertilizer before watering will encourage growth. Before earthing up any, a slight dusting of powdered lime around the plants is beneficial. Spray often to prevent rust. Dusting is probably better than spraying for this fungus. Thin out the lettuce. In September a sowing of lettuce may be made in cold frames for later use and if one has plenty of frame space a sowing of beans, beets and carrots can also be made. Sowings of cabbage and cauliflower may be made during the same month to have an early batch in the Spring. Be careful not to allow sowings of beets or anything else to become over-crowded. They will grow much more rapidly at this season if given plenty of room.

Late corn will also need every encouragement to mature. Remove all growths at the base of the plants, and give them plenty of room.

Tie up endive at intervals of about ten days, just enough to keep up a succession, as it may go bad by decaying if too much is tied up at any one time.

Parsley should be transplanted into a cold frame right away, so that protection may be given it when cold nights arrive. Seeds may be sown for early Spring use, as parsley roots that have been grown all Summer will run to seed very early in the Spring. Sow also plenty of Prickly Spinach in vacant places where other crops have been removed.

As soon as the onion crops die down lift them and spread them out in the sun to get thoroughly dry before storing them for the Winter. Use the larger onions first as the small ones keep much better.

Be sure and sow cover crops on any vacant piece of land that is not required for late crops. When manure is scarce these crops, when plowed under, are a good substitute for barnyard manure, adding humus to the soil. A mixture of Rye and Hairy Vetch may be sown quite late in the season. We shall probably, in the future, have to resort more to this method of supplying the soil with organic matter than in past years. Already truck gardeners are finding great difficulty in getting enough manure for their needs, the motor vehicles doing away with so many horses.

Renovating of lawns, if such work is in mind, should be attended to early. Plough as deeply as possible; add plenty of manure and bone meal, cultivating thoroughly for some time before re-seeding. This will give the seeds of weeds a chance to germinate and be killed before the lawn is leveled and laid down.

In the fruit garden it is better to harvest the fruit before it gets dead ripe. Peaches, plums, etc., that have to be shipped some distance will arrive in very poor condition if shipped when fully ripe. Apples are also better if gathered before they begin to drop too freely. If a high wind rises as they approach the ripening stage, a heavy loss of fruit

will be the result, so it is better to pick them rather on the green side. A good, cool airy fruit room is necessary to keep fruit well, or for any length of time, and, of course, such fruit must be picked by hand. Careless picking means poor keeping quality. Peach trees that are affected with red spider should receive repeated syringings with the hose after the fruit is picked.

Keep cultivating around the raspberry canes and remove all unnecessary growth that may push up. Blackberries may also be looked after in the same manner. Get all young strawberry plants in their fruiting place before the end of August, if possible.

IN THE GREENHOUSE

In the greenhouse we have now arrived at a period when quite often, unless we are watchful, foundation can be easily laid for an attack of fungus diseases. The days are generally hot and quite often the nights are cool. A little fire heat is the best safeguard with plenty top air so that the air is continuously circulating inside the greenhouse. Have all syringing done early in the forenoon which gives a chance to the foliage to be dry before night.

It is now time to get the cutting bench ready for bedding plants for another year. Get a supply of good clean, sharp sand. If it is in any way dirty, it may be washed clean in a tub working a hose through it and allowing the dirt to wash over the side of the tub. If this is kept up for a few minutes the sand will wash fairly clean. Have the sand just deep enough on the bench to keep the cuttings steady. Geraniums and coleus do not like to be kept too damp while they are rooting. Water them well when they are placed in the sand and give them no more until they become quite dry. There are more geranium cuttings lost by watering the bench too often than from any other cause. They also are better kept quite airy.

Carnations that were benched early will, when the cool nights come, begin to make top vigorously. Do not remove any buds after the end of August—the 20th is about right to have flowers when they begin to get scarce outdoors. Keep the soil on the top of the bench stirred lightly and after watering and syringing, dust the bench lightly with air-slaked lime. Watering and syringing should be done at the same time and then the bench should be allowed to get dry. It is advisable to add another wire as the stems lengthen.

By the end of the month buds may be taken on the Chrysanthemums. They must be fumigated quite often to keep them perfectly free from green or black fly, which generally lay their eggs in the leaves that are undeveloped on the point of the shoot. Until the bud sets, they have to be gotten rid of as the leaves unfold. Feed them liberally but do not overdo it. A leaf will break with a snap when they are getting enough. When syringing is done, do it as early in the day as possible. Soft coal soot water is good for the foliage and, then, insects do not relish it.

Buddleya Asiatica may now have their final potting. If one has a very cool house, with just enough heat to keep it from freezing, this plant can be carried over until very late in the Spring. It is excellent for cut flowers, taking the place of *Stevia*; therefore have a good batch.

When September arrives, herbaceous *Calceolarias* will begin to grow freely; give them every advantage, keeping them close up to the glass and only give a slight shade if the sun is hot. The shrubby type of *Calceolaria* will not have done much during the hot weather but if now given attention will begin to grow freely. When an inch or two of soft growth is made, they will propagate quite easily. Large specimens may be grown from the kept-over plants if pinched into shape during the Winter. Pot *calceolarias* in a good fibery loam, adding equal parts of flaky leaves, well decayed horse manure and sand. Do not pot them too firmly.

Never allow the *Unerarias* to become pot bound until they are in their flowering pots. When potting add bone meal to the compost. We grew plants last year in a small cool pit without a bit of heat, and they flowered as late as May. In fact, we put the last one on a piazza the first week of June.

It is now time to overhaul *Pelargoniums*; cut them well back and reduce the ball and repot in smaller pots. They delight in a fairly heavy soil. Grow them very cool and close to the glass.

Start the *Calla* lily bulbs any time now, they enjoy a rich soil. If grown in pots, about four bulbs to a nine-inch pot, is about right. They do better planted out on a bench, if space is available.

If the *Bouvardias* have been planted outdoors all Summer, it is now time to lift and pot them. Place them in the shade when potted, and spray them lightly until they grip the soil in the pot. They should be housed in the greenhouse by the middle of September. A rather rich compost with plenty of leaves mixed through it is best for them.

I saw a nice bench of *Streptocarpus* last Spring. This is a good time to sow these beautiful hybrids on finely sifted sphagnum moss, in heat, and grow in a temperature close to sixty degrees. They stand a lower temperature when flowering. Give them a compost similar to *Begonias*. *Streptocarpus* are very subject to mealy bug, but that insect may be kept in check by fumigating with hydrocyanic gas, one-half ounce to the thousand cubic feet. *Canterbury bells* always come in useful as a Spring flowering plant in pots. Go over the Spring sown batch and pick out as many of the largest as can be accommodated.

Late flowering *Cosmos* are very useful in the Fall. If they have not been grown in pots, plants that have been planted out may be lifted. If they are quite dry at the roots, they will soon recover from the operation.

Pot up successive batches of *frezia*. The colored ones are best for late work. If kept in light, and cool all Winter, they will flower as late as June. The early potted white variety will flower for Christmas in a rose house temperature.

Late struck *Poinsettia* cuttings make nice dwarf plants, ten or a dozen to an eight-inch shallow pan. Have them growing close up to the glass, which tends to keep them short and sturdy.

Get the place for the violets ready as they have to be in their Winter quarters by the middle of September. They delight in a heavy, rich loam. A friend of mine grows his violets in seven-inch pots in a small pit without any fire heat. He picks flowers all Winter, and in the Spring there is just a mass of flowers, making them useful for pot plants.

By the end of August the rose house is better if given a little heat circulating in a pipe or two, at the same time leave plenty of air on. They may now have a top-dressing of bone meal. Syringe in the early morning, and have as little moisture as possible over night. A dusting of air-slaked lime in the evening keeps the air sweet.

Very often around September 10, we have an early frost so that it is wise to make preparations to house all plants that are affected by light frosts, should a cool night threaten. *Azaleas* stand quite a frost, but their flower buds do not, so that if frost touches any, we are very likely to lose a season's flowers. These plants are now setting their flower buds, and any feeding that would encourage growth, should now be discontinued. Occasional waterings with soft coal soot water will keep the color on the foliage until they flower. This also applies to *Acacias*, *Camellias* and other hard wood plants.

Examine the *Begonia* plants; the stronger and larger plants may receive another shift if larger specimens are

Hardy Bulbs for Fall Planting

H. E. DOWNER

THE announcement made by the Federal Horticultural Board some time since that the importation of such bulbs as *Scilla*, *Muscari*, *Galanthus*, *Chionodoxa*, etc., would be again permitted was very gratifying to all those who love these beautiful Spring flowers, but the concession is limited to only three years, after which they are to be excluded again. At that time, also, the prohibition against bulbs is to be extended to *Narcissus*. Everyone, therefore, who has a garden would be well advised to plant these bulbs as generously as possible during this open period.

There are few places indeed where serious effort has been made to realize to the fullest extent their beauty and charm, and certainly no plants can surpass them in ease of culture. Outside the purely formal garden, the more informally they can be arranged the better. To see big drifts of Squills, Crocuses, or Daffodils flowering through the grass is a picture to be always remembered with pleasure, and such pictures could be displayed for the benefit of thousands of people in our public parks and gardens at comparatively small expense. In a small garden I know, containing many rare and beautiful plants, are some nice old apple trees beneath which in the early Spring there develops a picture of wondrous beauty. First comes the Snowdrop, pale but beautiful, and then the gay flowers of *Crocus*, *Scilla* and *Chionodoxa*. Thousands of these little bulbs are intermingled and very happy in a few square feet. After the foliage has ripened the mower is brought into play and this former patch of unusual loveliness is just lawn the rest of the season. One need not be a millionaire with extensive acreage to duplicate that.

Although the planting season is some time ahead, it is none too soon to be planning. If dormant bulbs could be had in the Spring the bulb business would increase, as we often meet people who would so love to have some in their garden but forget all about planting until they see them in bloom. Most bulbs are not very particular as to soil but they do appreciate a good soil with some body to it. It is not wise to use manure at planting time unless it is thoroughly decomposed. Leaf-mold is good, especially on heavy soil, and if it is thought that a little more assistance is necessary, bone meal is safe and much appreciated. There is no great reason for delaying planting after the bulbs are on hand, except sometimes force of circumstances.

If we dig up established bulbs in September we find they are well rooted. This brings up the question of planting bulbs in the herbaceous border and allowing them to remain from year to year. To my mind an herbaceous border is not complete without a good assortment of bulbs planted informally throughout. Their flowers show off well amongst the fresh young growth of the later flowering perennials, their ripening foliage is not conspicuous, and any gaps they leave can be well filled with annuals. There comes a time, however, when the border needs renovating and it is usually the middle of October before this can be done. I have never hesitated to dig up and divide the clumps of bulbs at that time, or even later, and have yet to see any ill effects from so doing. It is important, of course, to see they are not allowed to dry out while the changes are being made.

It often happens that Daffodils and Tulips are not planted deep enough; they should have at least four inches of soil over them. Another little detail worth looking after is to make sure that the base of the bulb is resting on soil. For all but the smallest bulbs, a broad trowel is

a better tool to use than a slim one or a dibble. As a Winter covering for beds, pine needles are very good, being easily cleaned off in the Spring and not heavy enough to interfere with the pushing young growth. Half decayed leaves are excellent for this purpose also. When planting in sod it pays to make generous sized holes to allow of some prepared compost being placed under and over the bulb. The art of planting in grass is to make it appear that, like Topsy, they "just grewed." Anything resembling studied regularity is not nearly so pleasing. The important thing after flowering is not to cut the grass until the foliage has ripened off.

How encouraging it is, in the days when we seem to have had more than enough of Winter, to find the first Snowdrops in bloom. This dainty little barbinger of Spring is equally at home in the rock-garden, clumped in shady places in borders or scattered in grass. *Galanthus Elwesii* is a giant Snowdrop compared with the common *G. nivalis*, and is apparently more difficult to obtain. The Winter Aconite, *Eranthis hyemalis*, is usually listed with bulbs and a very cheerful little plant it is with its bright yellow flowers and good clean foliage. It is quite happy in moist places beneath the shade of trees and shrubs. A little edging of Crocuses is very attractive in a front yard, but spread with a lavish hand in grassy places, they produce a marvelous effect. One of the special Spring features in the famous Kew Garden is the display of Crocuses in the grass. The newest varieties are much advanced in size. *Crocus Imperati*, *C. biflorus* and *C. susianus* are species, smaller flowering but earlier than the hybrids and are well placed in the rock garden. The small Squills, *Scilla sibirica* and *S. bifolia* are very lovely when thickly planted in grass, and if left alone in borders they increase quite rapidly. As a contrast to their flowers of deepest blue, a little of the white variety can be interspersed with good effect. *Scilla campanulata*, the Wood Hyacinth, is a larger and later type in colors of white, pink, and blue, very good to clump in shady places.

A small bulb not commonly seen is *Puschkinia scilloides*. It has white flowers lined with blue, closely resembling the small Squills to which it is an excellent companion.

The Glory-of-the-Snow is too lovely to be omitted from any Spring garden. With its blue and white flowers, hanging loosely from the stem, it gives a very charming effect in the rock garden, borders or grass. *Chionodoxa Lucilliae* is the species generally planted, but the variety *grandiflora* has a much larger flower.

The Grape Hyacinth, *Muscari botryoides*, prolongs the season of blue and thrives well in practically any situation. The variety Heavenly Blue, is best, and there is a white variety which is very good for contrast. The Feathered Hyacinth, *M. monstrosum*, is an interesting oddity with its plume-like flowers.

The Guinea Hen flower, *Fritillaria meleagris*, would be a novelty for many and is a most interesting plant for the border or wild garden. The nodding, cup-shaped flowers are curiously striped and checkered in shades of yellow, white, and purple. Outside of real old-fashioned gardens, the Spring Snowflake, *Leucojum vernum*, is seldom met with. It resembles a glorified Snowdrop, a few weeks behind time, and is excellent for naturalizing and grouping in borders partially shaded.

Triteleia uniflora makes a very attractive edging along a warm sunny border with its pretty star-shaped flowers of white shaded to violet.

Daffodil time is a beautiful time in the garden, and

popular as the Daffodil is, a still more liberal use could well be made in most gardens. Few flowers show to better advantage when naturalized than the various forms of Narcissus. Along woodland walks, on banks, and in any piece of grass that is not good lawn, they display their charms to perfection. Planted about a pool or lake, their effectiveness is enhanced by reflection, and against evergreens they show up wonderfully well. In my boyhood surroundings, the Daffodil was a common wild flower and ever since I have preferred to see it looking as natural as possible. The several divisions and sub-divisions into which the Narcissus has been classified often leads to confusion, and many a Garden Club meeting could be enlivened by an innocent inquiry as to the difference between a Daffodil, a Jonquil, and a Narcissus. This confusion has not been recently brought about by the introduction of the numerous modern varieties as might be supposed, for Parkinson wrote three hundred years ago that "There hath been great confusion among many of our modern Writers of plants, in not distinguishing the manifold varieties of Daffodils"—and again he writes "Many idle and ignorant Gardeners doe call some of these Daffodils Narcissus, when as all know that know any Latine, that Narcissus is the Latine name and Daffodil the English of one and the same thing."

Such small flowered species as *N. bulbocodium*, *N. cyclamineus* and *N. minimus* are gems for the rock garden, their dainty flowers appearing very early. The true Jonquil, *N. jonquilla*, is well placed in the rock garden also, but the stronger kinds hardly belong there. Narcissi that have been flowered in pots should not be thrown away. A good place for them is in the shrub borders where they will be quite happy and give much satisfaction. It adds to the interest to have the different sections represented and to try out some of the lesser known varieties.

In the Trumpet section, where the crown is at least as long as the perianth, Golden Spur, Emperor, King Alfred, Van Waveren's Giant and Lord Roberts, yellow; Mme. de Graaff and Loneliness, white; Duke of Bedford, Empress, Glory of Noordwijk, and Victoria, bicolor; are all first-class varieties.

In the *Incomparabilis* or chalice-cupped section, where the cup or crown measures up to three-fourths of the perianth, Great Warley, Sir Watkin, and Lucifer make a good trio.

The old reliable *Conspicuus*, Lady Godiva and Red Beacon represent very well the *Barrii* group, in which the crown measures not more than one-third the length of the perianth.

The *Leedsii* section is similar in form to the *Incomparabilis* and *Barrii* groups but the flowers are all either nearly white, or white and pale yellow. Mrs. Langtry, Duchess of Westminster, and White Lady are three of the best known varieties. The *Poetaz* group are hybrids between the *Poet's* and the *Polyanthus Narcissus*, a very sturdy free flowering race of good lasting quality. Three good ones are *Admiration*, *Elvira* and *Mignon*, which bridge the gap between the Trumpet Daffodils and the Darwin Tulips very nicely.

N. poeticus is distinguished by a pure white perianth of good substance and a flat wide cup shaded red on the edge. The old-fashioned Pheasant's Eye is worth planting in large quantity for naturalizing. *Ornatus*, King Edward VII, and *Glory of Lisse* are improved varieties.

Between the Daffodils and the Darwin Tulips, the stately Hyacinth seems likely to be receding in popularity. Its special place is in the purely formal garden where regularity is the keynote, but uniform rows of plants outside the vegetable garden are not regarded with much favor nowadays. However, the stiffness of a bed of Hyacinths can be toned down considerably by carpeting

with such Spring-blooming plants as pansies, English daisies, forget-me-nots and Arabis. Forget-me-nots under pink or white Hyacinths, and Arabis beneath a porcelain-blue variety are simple but effective combinations. They show to very good advantage in the shrubbery, if irregularly grouped along the front. Early planting in good loose soil at a uniform depth of about five inches are preliminary details it will pay to observe.

The Tulip is an old established garden flower at present riding on a high wave of popularity. Parkinson in his "*Paradisus Terrestris*" (1629) described and figured many varieties. He classified the early-flowering group into forty varieties, embracing four colors; a middle-flowering group into sixty-five varieties, also under four colors; and a late-flowering group of five varieties. In these days, the early-flowering section has been eclipsed in the outdoor garden by the later Darwin, Cottage, and Breeder types, wonderful flowers in all shades of colors. Welcome as the early Tulips are, we cannot spare the room for them in a small garden but prefer to wait for the later beauties that make up for their tardiness by remaining longer with us. All the space possible in beds and borders can well be given over to them, for they can be left undisturbed to ripen off, planting in annuals between them if need be. They can remain, on the average, about three years undisturbed.

It is very difficult to look over a good assortment of varieties when making up a planting list and decide which ones to leave out. We should like to have the room and the means to grow them all. At any rate we can have plenty of enjoyment by browsing through a good bulb catalog.

Cottage Tulips, so-called because re-discovered in European cottage gardens, are distinguished from the early flowering section by their longer and more graceful stems and slender flowers, some oval, others pointed and reflexed. They afford a wide range of color and the general effect in the garden is very charming.

The Darwins present a more stately appearance with their taller upright stems. The cup-shaped flowers are also of greater substance, and seem to embrace about every shade of color but yellow. Breeders, which are seedlings with a tendency to "break" into mixed colors, resemble the Darwins in habit and form. They give some of the most rare combinations of art shades to be found in any flower and consequently are becoming very popular.

In contrast to these late flowering giants are the smaller growing species. *Tulipa Clusiana*, the Little Lady Tulip, is a gem with pointed flowers of white, striped deep rose. *T. Greigii* is brilliant scarlet, a gorgeous flower with pointed reflexed petals. *T. Kaufmanniana* has wide open flowers of carmine and yellow, opening early in April, a real beauty. *T. præstans*, scarlet, also comes early and usually has more than one flower to a stem. The fragrant, clear yellow *T. sylvestris* is also inclined to this multiflorous habit. They are not happy or long lived everywhere, but are well worth experimenting with in rock gardens or favored spots in borders, and are sure to give unusual pleasure if they succeed.

He who said, "There is no sentiment in business" forgot that business everywhere is conducted by human beings.

That's why we say "Flowers in an office make a better business day." A cheerful atmosphere makes thinking easier and puts vim into languid muscle. Petals of color, stems of green; the presence of just a few fragrant flowers will make those who come, remain or go, believe that "This is indeed a place where effort is pleasure and work is joy."

Late-Flowering Azaleas

BECAUSE they are unable from a botanical standpoint to separate Azaleas and Rhododendrons, botanists include them all in the genus Rhododendron. The original broad distinction was the evergreen Rhododendron with ten stamens. When species were introduced with these characters reversed or which did not fall into either group, there was nothing to do but sink one of the names in the herbarium. The popular name of Azalea will always, we must hope, be retained to indicate the most

vance of the species, which is only natural when an early-flowering pollen-parent is used. To obtain the object in view, breeding must be systematically focussed on the raising of seedlings, and the crossing of the latest to flower, for several generations.

The one thing we may be "up against" in the raising of a race of late-flowering Azaleas is that they will be at their best during the hottest weeks of the year. We know, however, that the wild Azaleas grow in shady damp situations, and we should do well to follow Nature more in our planting. The Cornish growers may have an ideal climate for Rhododendrons, which is half the battle, but they are also fully alive to the value of mulching. Here again we should follow Nature by mulching annually with leaves, using sticks to hold them in position. Rhododendrons and Azaleas are surface-rooting, with fine roots which drought will soon kill. Leaves keep the surface cool and moist in Summer and warm in Winter.

A peaty soil is by no means essential, for Azaleas thrive in a moist, loamy soil that is free from lime. Hard or close ground can soon be brought into condition by trenching and adding plenty of leaf-mould. While named sorts must be increased by layering, cuttings or grafting, the species can be freely raised from seeds. Much more should be done in the raising of seedlings from hybrids for woodland planting. The probability is, in such case, that these will give a wide variety, while there is always the possibility of something even better than the named parent plant.

(Courtesy of The Garden)

The White-Flowered "Swamp Honeysuckle," *Rhododendron viscosum*

beautiful family of hardy deciduous flowering shrubs cultivated in our gardens.

Most of the varieties are at their best from late April to early in June, with a wonderful wealth of blossoms during May. These notes are intended to draw attention to the possibilities of a race equally rich in colors, flowering from mid-June and throughout July. We already have several species flowering at this season, beautiful in themselves and with a delicious fragrance, but they lack the rich and varied shades of color so charming in the Spring

(Courtesy of The Garden)

The Flame-Colored *Rhododendron calendulaceum*

and early Summer-flowering hybrids. Some crossing has been done with these species already, and especially with *R. occidentale*, but the hybrids invariably flower in ad-

(Courtesy of The Garden)

The White-Flowered Form of *Rhododendron occidentale*

RHODODENDRON OCCIDENTALE.—This species was first introduced from Western North America, about the middle of last century. It is the best of the late-flowering section, being at its best about Midsummer Day and lasting well into July. For planting in open woodland with, possibly, a running stream we can scarcely wish for anything better. There are forms with white flowers and a yellow blotch, and others of pleasing pink shades. The deepest form at Kew is labeled *R. occidentale* var. *roseum*. By crossing this species with some of the earlier-flowering section Anthony Waterer has raised a number of hybrids with light-colored blossoms.

Not the least desirable character of *R. occidentale* is that flowers and foliage develop together, and added to this is a delicious fragrance. Eight to ten feet appears to be the ultimate average height of large bushes.

R. viscosum.—The white Swamp Honeysuckle is one of the last of the deciduous Azaleas to flower. Commencing in late June, the bushes blossom throughout July, the flowering period even extending into August in late districts. The flowers being among the smallest of the Azalea family, the name of Swamp Honeysuckle is most appropriate for this species. The color varies from white to those with buds and blossoms daintily tinted with pink. The delicious fragrance appeals particularly to ladies, and when this species is planted in sufficient quantity the scent is powerful enough to pervade the air.

R. viscosum was first introduced from Eastern North America in 1734. As a wild bush it favors the moist ground and swamps of Maine and Kentucky, its distribution extending from Canada to the Southern United States. Young plants commence flowering when one foot high and blossom each year with unerring freedom until the twiggy bushes are six feet to eight feet or even ten feet in height. The viscid or clammy character of the flowers is more pronounced in this species than in any other species of the American group.

The old florists are reputed to have used this species freely in raising the hybrid Azaleas of the first half of the nineteenth century, but in the desire for large flowers more attention has been given to *R. molle* and *R. sinense* as parents, with the unfortunate loss of much of the pleasing fragrance. Some of the oldest bushes in the Azalea Garden at Kew in the white, pink and rose tints of the flowers, fragrance and viscid character suggest *R. viscosum* as one of the parents.

R. CALENDULACEUM is the flame-colored Azalea of Eastern North America. It is a widely distributed species, and variable in the color of the flowers (red, orange and yellow) and the season of flowering. This is the species from which the rich coloring in many of the Ghent Azaleas was obtained. The early flowering of these hybrids suggests that the *R. calendulaceum* used was the form flowering in May or early June. Seedlings of more recent introduction are at their best about the middle of June. With their rich orange-colored flowers this form should be a valuable one to cross with *RR. viscosum* and *occidentale*.—*The Garden* (British).

GREENHOUSE AZALEAS

THE greenhouse Azalea is one of the most popular of indoor plants. With fair treatment and reasonable attention to their well being, the plants never fail to do well, and to outlive the greater portion of other hard-wooded kinds grown in pots. In fact, Azaleas are amongst the longest lived of the various tribes of greenhouse plants. In proof of this I may instance several large collections that are in the hands of some of the market growers near London, many of the specimens in which are known to be fifty years old. They consist mostly of the old white (*indica alba*) and Fielder's White, which is only slightly different from the original sort. The plants in question are full of vigor, and make shoots from eight inches to fifteen inches in length annually, only a small percentage of which fails to flower.

The weakening effects which turning out of doors has on plants whilst making their growth may be seen in hardy shrubs that have been flowered in pots under glass when treated in this way; the partially-formed shoots do not thicken, the immature leaves look yellow and sickly, and when the plants are again planted out and fairly cared for it usually takes two years to bring them round. It may be said that there is some plea to justify this way of treating Azaleas, inasmuch as most of what has been written on their cultivation is to the effect that the turning-out process is the right course to follow.

Another source of weakness that Azaleas, in common

with most other hard-wooded plants, suffer from is want of sufficient nutriment. In the case of pot plants of the numerous kinds that bear partial shaking out and re-potting annually, the old material which has become exhausted is gotten rid of and is supplied by new. With Azaleas and other things of like description, the nature of which is such that they will not submit to be treated in this way, the roots remain for years in the same soil, and unless something is done to make up for what the roots extract from it the whole becomes so poor that the plants cannot do more than exist in it. This especially is what takes place with old specimens that, after being put into pots as large as it is convenient to give them, shortly become dependent on what they receive in the shape of manure in some form. That old Azaleas can be kept for any length of time full of strength and vigor I have proved with specimens that have remained undisturbed in the same soil for ten years, and at the end of the time they made as much wood as when they were young. It may be well here to say that peat of even the best quality is not rich enough to enable Azaleas to make the growth they should do. The assistance that is required in this way to either get young Azaleas on quickly or to keep up the vigor of old plants is much more than seems to be generally supposed.

When ordinary manure-water is used for old specimens it should be given once a week during the time that the plants are making their growth, and up to the time the wood is approaching a hard, mature condition and the buds are prominent. After this stage has been reached it is doubtful if manure in any shape does not do more harm than good.

Regarding the new varieties of Azaleas, many of which have been sent from the Continent within the last score of years, it is doubtful if, taking all their properties into account, they are any improvement on the well-known older sorts. Some of them are an advance in the color and also in form of their flowers, if we accept the florists' circular outline as the standard to aim at. There is a long list of kinds in cultivation, which any good nurseryman's catalogue will supply. —*Gardening Illustrated*.

IN THE GARDEN AND GREENHOUSE

(Continued from page 194)

desired. The closer they are to the glass the better they will grow.

Crotons will take very little shade over them by the middle of September. Do not let water lie on their foliage for any length of time. To keep them free of insects, a thorough syringing with some standard insecticide once every ten days is sufficient. Mealy bug may be taken care of by fumigation with hydrocyanic gas. Crotons that lose their foliage during the Fall and Winter have been kept too wet overhead and at the roots. To grow them well a small house should be devoted to them.

Cattleya labiata is now finishing its growth, and by the middle of September any shading that is over it should gradually be removed. Cross bred orchids flower at all seasons, and are not like many of the species, which can be potted at certain seasons. As soon as any of them begin to show new roots, if they need a shift, they must be attended to. It is better to keep them slightly closer as regards atmospheric conditions, after potting. Also be more careful in watering until they are again established.

Grapes will now be ripe or fast approaching that state. Give abundance of air and keep a dry atmosphere until they are all cut. Pot vines that were forced early may now be gradually dried off. Just give enough water to keep the wood plump and firm. A few degrees of frost is good for them as they force the better after it.

Notes from an Old Country Garden

ARTHUR T. JOHNSON, F.R.H.S.

IN the June issue of the GARDENERS' CHRONICLE William N. Craig has some interesting notes on azaleas, and I am glad to hear that that fine American species, *Vaseyii*, is as popular in its native land as it is with us. There is, as Mr. Craig says, something extremely charming about this beautiful shrub, with its blush-pink, or pure white, blossoms, and it is a reliable bloomer every April with us. *A. viscosum*, the Swamp Honeysuckle, a compatriot of *Vaseyii*, is hardly less lovely and exceedingly fragrant. This fine species was very largely used by the

Romneya Coulteri

old hybridists, and many of our sweetest and best garden forms we owe to it. Much later in flowering than the foregoing, the blossoms of *A. viscosum* synchronize with those of the latest of all, the Californian *A. occidentale*. Being a deciduous species and one that flowers in July this azalea should prove as hardy as most of those usually considered frost-proof, and it makes a most delightful, loose-habited bush bearing good-sized, fragrant blossoms in a pure white, sometimes shaded with a rosy flush. I cherish many glorious memories of California's flower-filled valleys, but none of them are more vividly recalled than those of shoulder-high thickets of *A. occidentale* whose thronging masses formed the greater part of the undergrowth of a vast forest of deciduous oaks. Like so many of North American azaleas this Californian species has proved a first-rate "breeder" and to it also we are indebted for many of our most delightful late-flowing hybrids.

Another most fascinating little shrub among the Summer-blooming azaleas is *Rhododendron azaleoides*, and this again, though partly evergreen in some districts, may be considered deciduous and hardy enough for the bleakest climate Western Europe affords. Indeed, when one considers that the parents of *R. azaleoides* were *Rhododendron maximum*, the Great American Laurel, and the above-mentioned *A. viscosum*, one has a combination which suggests extreme hardiness and reliability. This pretty shrub, which grows up to three to four feet, usually opens its

flowers here about mid-June or later, and the large and bold trusses of white, lilac-tinted blossoms, which are most deliciously scented, then "carry-on" for many weeks during full Summer.

American shrubs are so much in evidence in my garden just now that I could hardly do better than refer to one or two more. One of these is that old favorite *Kalmia latifolia*. Though introduced two centuries ago this magnificent shrub is not yet commonly known. But it holds its own amid the influx of novelties and nothing will ever imperil the foremost position it occupies among the choicest of our Summer-blooming evergreens. The waxy, rosy-pink, pentagonal flowers are singularly lovely and this species is the only one of the *Kalmias* which is really prosperous in our rather dry, loamy soil, the others appearing to be more dependent upon a peaty medium. The flowers of *K. latifolia* are as interesting as they are beautiful, for if the point of a pencil is inserted into the centre of a blossom it will be noticed that one or more of the five stamens, each of which is bent back against an angle of the corolla, will be released and, recoiling like a steel spring, send a little puff of yellow pollen into the sunlit air.

Carpentaria Californica is hardy enough for any of our counties which enjoy a sea-influence and its rich green foliage and large, anemone-like, fragrant flowers make a rare combination. This is a lime-loving shrub which likes a warm, freely-drained soil no less than do its near relations the *Philadelphuses* (Mock Orange). We grow a goodly number of these latter, for they come into flower at a time when all the Spring things are over and, being practically drought-proof, they suit our light land. Here one can not do more than mention a few of the best, and I think the pure white, double-flowered, *P. virginal* must be accorded first place. This is a most striking shrub of some eight feet in height, the leafage is a deep green and the very large flowers, with their prettily incurved petals, are extremely chaste and refined. *P. grandiflorus* of the Southern States of America might be described as a greatly improved coronarius, the blossoms being whiter and the slight fragrance more delicate than those of the latter. Then there is the excellent hybrid, *P. voie lactee*, with single, milk-white blooms of great size and firmness of texture, and several varieties with purple-blotched petals, suggesting a *Cistus*, which are offshoots of the Mexican species, *P. Coulteri*. *P. Lewisii* is a N. W. American species whose great and distinct merits have not yet been fully appreciated on "this side," and the pretty *P. hirsutus* of California appears to be a more tender form of the same thing.

When *Fremontia Californica* goes over towards the end of July the great *Romneya Coulteri* opens the first of its superb blossoms, and from that time onwards to the season's end it stands unrivaled among the noblest subjects in the garden. I need not point out to American readers the outstanding magnificence of *R. Coulteri*, nor the singular beauty of *Dendromecon rigidum* which blooms at the same time. But there is another sub-shrubby plant which is grouped with the above in this garden, and which also is in flower at the time of writing, and that is *Lavatera olbia*. This is probably the most beautiful of all the mallows, a robust, sub-shrubby perennial which makes a large bush some four feet in height and five feet through with thick and hairy vine-like leaves. The flowers which crowd the elegant growths of this plant and which bear no little resemblance to those of a single Hollyhock are a fresh, silvery-pink deeply rayed with a rosy carmine. *L. olbia* will

flourish in any soil or situation which suits the *Romneya* and, like the latter, it is best cut hard back to the base in Spring.

Of the many fine shrubs and trees sent over by Mr. E. H. Wilson none is likely to create a more notable and enduring effect than *Spiræa* (*Sorbaria*) *arborea*. This splendid species, which hails from China, is easily the crowning triumph of its race and one for which the best place in the garden will never be too good. *S. arborea* belongs to the ash-leaved group of shubby meadowsweets, and it will attain the dignity of a small tree, sending up a number of tall, gracefully arched, whip-like branches with ruddy stems and very large, pinnate leaves. Towards the end of Summer these elegant branches terminate in enormous flossy plumes of creamy-white inflorescence which droop with the weight of their innumerable flowers with the most graceful effect imaginable. This admirable spiræa grows fast, needs plenty of space to display its singular loveliness and, though not fastidious as regards soil, a fairly rich and moist medium appears to suit it best.

Perhaps the most striking of all climbing plants of late Summer, and one that will continue to give color until the first frost comes along, is the Flame Nasturtium (*Tropæolum speciosum*). This gorgeous subject, though a South American, will, however, not prosper in all our gardens. Strangely enough it dislikes the warm south and flourishes most abundantly in Scotland where it has become naturalized in some parts. Here, on the west coast, we grow it on north walls, or among such shrubs as azaleas, zenobias, pieris and others which enjoy cool conditions, and it rewards us throughout the later months of the season with its abundant masses of brilliant scarlet flowers. Once established *T. speciosum* needs no more attention. It will sink its fleshy roots to a great depth and every year with unfailing vigor wreath and garland its supports with its wonderful ropes of color. Then as the flowers fade the seed ripens to a vivid china blue and, if propagation is to be effected by that means, sowing should be done at once, i.e., in the Fall. Roots are best planted in Spring, just when they begin to show signs of activity and they should be laid not less than nine inches deep. How the Flame Nasturtium stands the Winters of Eastern America I do not know, but in this country it is hardy enough to endure without injury the severest conditions.

Considered as a group the Evening Primroses (*Oenothera*) must always be accorded the highest merit among the herbaceous plants of late Summer, and among these I do not think any can excel the old *O. biennis*. Given a good form (*Lamarckiana* or *grandiflora*) this splendid subject will send its elegant stems to a height of four to five feet and bear a long succession of its lovely flowers. These, as most people are aware, are cup-shaped, some three to four inches across, very sweetly scented and a clear lemon yellow which is always so telling a color in the evening border. Though a biennial this species regularly keeps us supplied with a sufficiency of self-sown seedlings.

Less than half the height of the above is the perennial *O. fruticosa*, with its admirable forms, *Eldorado* and *Youngii*. These Evening Primroses are among the most reliable of their family in practically any soil, and their crimson buds and rich golden-yellow flowers are very striking. But when we come to these dwarfier species from the more westerly States of America and Mexico a free, warm soil and not too hard a climate are essential. The best known, and possibly the hardiest, of these is *O. Missouriensis* (*macrocarpa*) a trailing, herbaceous species whose flowers, like great goblets of gold, often five inches in diameter, are produced throughout the later months of the season. *O. taraxacifolia* might be described as a white form of the above, but it has deeply-toothed leaves and the trailing flower stems may extend a yard or more. Even more abundantly beautiful is *O. caespitosa* (*marginata*)

which, instead of trailing, sends up at intervals from underground stems tufts of gray-green, crimson-ribbed leaves with wavy margins. The flowers of this species are the largest of the family, often being six inches across. They are pure snow-white and emit a delicious magnolia-like odor. Another excellent species, also a native of North America, is *O. speciosa*, a sub-shrubby plant with rosy-pink flowers, and *O. arendsi* (eight inches) is apparently a hybrid from this, and a very good one too. The midget of the group is *O. pumila*, a wee, rock-garden plantling of about four inches, which maintains a succession of bright yellow flowers from May to October.

Though there are many other excellent kinds among the *Oenotheras* the above are those most generally grown over here. American botanists have, I believe, undertaken a complete re-classification of the Evening Primroses, but of this I can claim no exact knowledge and make that my excuse for adhering to the old nomenclature.

THE SHRUBBY SPIRÆAS AND THEIR CULTURE

THE genus *Spiræa* contains some sixty to seventy bushy or shrubby species and a very considerable number of varieties. For garden decoration, however, twelve, or in extensive shrubbery borders twenty to twenty-five, species or varieties would provide a representative collection. They vary in height from the six inches to the nine inches of *S. decumbens* (*procumbens*) to the twenty-five foot to thirty foot of *S. arborea* and *S. Lindleyana*. Few families of shrubs provide such a lengthy season of flowering, which extends from March to October. The *Spiræas* are natives of Europe, North America and North Asia. A large number have white blossoms, and, mostly among the Summer and Autumn flowering kinds, those with pink and red blossoms are beautiful.

Obviously, shrubs which vary so much in stature and produce such a profusion of blossoms should be extensively planted not only in the borders and as single lawn specimens, but in large groups and masses in the pleasure grounds and on the boundaries of woodland. Some of the *Spiræas* are also adapted for waterside planting.

The cultivation of *Spiræas* presents no problems, and for this reason we seldom see their full beauty. The first desirable items are an open position and a loamy soil inclined to be moist rather than dry and sandy. This, however, is not all. In the fruit garden we trench and manure the ground for Gooseberry and Currant bushes, giving them also an occasional mulch of decayed manure. The shrubby *Spiræas* revel in such treatment, making plenty of young growths, which are the heralds of an abundance of blossoms. If, in eight or ten years after planting, the bushes show any signs of weakening, lift them and trench the ground—planting a fresh stock, or the healthiest pieces from the clumps lifted.

Scarcely too much stress can be laid on the importance of pruning *Spiræas*. Broadly speaking, they divide naturally into two large groups for purposes of pruning: (a) those which flower in Spring on the growths of the previous year and (b) those which flower in Summer and Autumn on the current season's growths.

The correct treatment for group (a) is to thin out the older wood and weak twigs as soon as the blossoms shatter. This serves to encourage vigorous new growth at once. If through any cause the bushes become tall and straggly, sacrifice a season's flowering and cut the shoots hard back in March.

Group (b) is best pruned in February or March. First remove old wood and weak shoots which can be entirely dispensed with, shortening back the remaining vigorous wood so that the resultant young shoots form shapely bushes—*The Garden* (British).

Rambling Remarks on Shrubs and Trees

FLORUM AMATOR

TO this genus of shrubs, *Eleagnus*, is well given the common name, Silver Thorn, because of the silvery under color of the leaves. The thorns of this shrub happily are not real thorns, but thorn-like growths devoid of the sharp points of true thorns. The small fragrant, dull yellow or yellowish white flowers, which are borne in thick clusters along the branches, are not particularly pleasing to the eye. In addition, to the silvery under color of its foliage and the fragrance of its flowers, another still more pronounced characteristic of the *Eleagnus* is its wealth of salmon-colored, or as in some cases, red or mottled berries ripening on its different species all the way from June to October. These numerous barberry-shaped berries are not only attractive because of their brilliant coloring but are useful as well for making tarts and sauce, and for eating out of hand, children especially being fond of them in the last way. This shrub, however, is primarily planted for ornamental purposes and not as an edible fruit-bearing bush. Other valuable characteristics of the *Eleagnus* are its free growth in sandy as well as other soil, along the sea coast as well as in the interior, the fruiting of the different species in different months covering a long range of time, and the fact that there are both evergreen and deciduous species.

E. longipes is the most widely known species of *Eleagnus* and is the most esteemed for its berries, which are red, and over one-half inch in length, ripening in June just after strawberries and just before currants and raspberries. The neat foliage with its silvery undercolor and the red fruit of this deciduous shrub, which attains a height of about eight feet, make it most valuable in mass effects.

E. parviflora is an older species than *longipes*; its leaves are smaller but have the beautiful silvery under color which is so noticeable a feature of this genus. Another feature of *parviflora* is its stiffness of growth which suggests its use as a hedge plant; in fact, it is often so used. Its pretty mottled salmon edible fruit, not as large as that of *longipes*, is dead ripe in August. This fruit which has the same pleasing acid taste as that of the other species of *Eleagnus*, is eagerly sought by children.

E. umbellata has the usual dull yellow fragrant flowers of the genus. When, however, its mottled salmon berries, thickly studding its branches, are ripe in October, it surpasses in beauty all the other species. The tall growth and late fruiting of this species place it among the ornamental berried shrubs of Autumn. Taken all in all, it is an ornamental shrub worthy of being freely planted.

E. argentea is, we think, our only native species; the rest are nearly all from Japan. The specific name, *argentea*, emphasizes the silver under color of the leaves; its value as an ornamental shrub is well known.

E. Simoni is an evergreen, hardy with some protection as far north as Philadelphia. Besides its evergreen character, *Simoni* bears its deliciously fragrant flowers, Jasmine-scented, some say, in October. These occasionally set a few red berries which ripen in Spring. This late flowering habit puts it in a class with *Hamamelis virginica*.

Some species of *Fraxinus*, the Ash, are planted for shade either as single specimens in suitable locations or as street or park avenue trees, where Plane and Elm would be too large. One species is grown as an orna-

mental flowering tree and one is best grown as a shrub for its handsome foliage. Several species grown as shade trees are valuable as timber.

Fraxinus Americana and *F. viridis* are both grown as single specimen shade trees. *F. Americana* or *alba*, as it is sometimes called, the White Ash, may be distinguished from *V. viridis* in the following way: *Americana*, or *alba*, grows taller than *viridis*; its leaves, which are retained much later than those of the latter species, are a grayish green on the under side and its seeds are in the lower and plainly bulging ends of the samara, or wings. *F. viridis*, on the other hand, has leaves of vivid green on both sides, which it sheds earlier than *Americana*, and its seeds extend half way up the samara, or wing, which does not bulge but tapers into a needle-like point. *F. Americana* is really the better tree because it holds its foliage longer. The planting of the White Ash as a lawn or street tree would be no experiment, as it has been used for that purpose and given entire satisfaction. Besides these shade tree ashes, there are *F. pubescens*, considered by some a variety of *F. Americana*, but smaller and with leaves of a reddish under color; *F. quadrangulata*, the Blue Ash, and *F. sambucifolia*, the Black Ash. The last two named may be planted with *Americana* for variety and, like the latter, are also valuable timber trees.

Then there is the European Ash, *F. Excelsior*, which is a good tree to plant as a single specimen in a suitable location, and its variety, called *aurea*, on account of its golden yellow bark which, as is the case with most trees with bright colored bark, is highest colored in the Winter.

F. aucubæfolia, so called because its leaves are yellow and green like those of *Aucuba variegata*, is best grown as a shrub or dwarf tree, since, when so grown, its pretty foliage—which, by the way, is best in Spring and early Summer—shows to far better advantage.

F. ornux, the Flowering Ash, the only species grown especially for its floral display, attains a height of only twenty or thirty feet. In June this Ash bears a wealth of handsome flowers, every twig being crowned with a cluster of fleecy white blooms. Hence it well deserves its name.

There are many species of *Euonymus*, some deciduous, others evergreen, growing mostly in shrub but some in tree and vine form. Generally the *Euonymus* is hardy, especially along the coast, south of the state of New York. The handsome foliage of the evergreen species, the berry-bearing habit of this genus, and the close clinging feature of the vine form make the *Euonymus* desirable for planting.

E. japonica comes to us from Japan, and is one of the most attractive of the broad-leaved evergreens; its shining green leaves and red-berried fruit strongly commend it to favor. In the north, it is better planted in sheltered locations, and for this reason is a good shrub for city gardens. Fine specimens of this species may be seen in southern New Jersey and in sea shore gardens from New York south. There is a beautiful variety of *japonica*, namely, *aureo-marginata*, whose glossy green foliage is margined with gold. There is another variety of *E. japonica* named *albo-marginata*, whose handsome evergreen leaves are edged with white. *E. japonica* and its varieties thrive in sandy soil, and are valuable, therefore, for sea shore planting. They are also excellent subjects for growing in tubs and pots.

E. Sieboldii, or *Sieboldiana*, is classed as an evergreen, but only retains this character in the South; in the North it drops its foliage when severe frost touches it. This species differs much from *E. japonica*, for its deep green leaves are not as thick and shining; its habit of growth is more bushy and its berries are orange-red.

E. alata is deciduous; the cork-like bark of its branches are four-winged; the almost innumerable red pods contain seeds covered with orange-red flesh, the display of which in contrast to its green leaves forms a bright picture. The flowers of *E. alata*, like those of all *Euonymus*, are greenish and not especially attractive. Its fruit and foliage are the beauty features. Sometimes in Autumn, the foliage assumes pleasing shades of color, just before it falls.

E. Americana is a native deciduous species, as is also *E. atropurpurea*, generally known as the American Burning Bush, but the latter is superior to *E. Americana*, which grows to a height of six to eight feet. Its branches are slender and very unlike those of *E. atropurpurea*, and its bright crimson seed capsules are warty, while those of *atropurpurea* are smooth and disclose on bursting bright scarlet seeds. The bright capsules and brilliant colored fruit within are the most attractive features of these species which commend them to planters of shrubs. They also explain the common names of Strawberry Tree, Strawberry Bush, Burning Bush and Bursting Heart, the first name being applied especially to *E. atropurpurea* when grown in tree form.

The European *Euonymus*, *E. Europæa*, brought in early days of American gardening from Europe, is still common in old gardens. The orange-scarlet color of its fruit helps to distinguish it from *E. atropurpurea*, whose fruit is of a deeper scarlet.

There is a comparatively little known *Euonymus*, namely *E. Hamiltoniana*, whose leaves are larger than those of *E. Europæa* and retain their color and form till late Autumn. The berries also of this species are of unusual beauty, the capsules which hold them being pink and the fruit orange-red.

Passing from the shrub and tree shapes of *Euonymus*, we come to a vine form, *E. radicans* and its variety, *variegata*. This species is a hardier vine than *Hedera helix*, English ivy, and very suitable for covering low walls and trunks of trees, but is a slow grower. It is a native of Japan, an evergreen, and clings closely and smoothly to stone, wood, or tree bark, but does not give the large effect of English ivy. We could not consider *E. radicans* and its variety rivals of the English ivy, but rather as a vine to be used when growth less luxuriant than English ivy is desirable and when the latter is not hardy.

We have used in spelling the generic name the older spelling, *Euonymus*; but the spelling more recently adopted is *Evonymus*, *v* being used in the first syllable instead of *u* as formerly. The later spelling appears to be etymologically correct.

The *Halesia*, Snowdrop Tree, is one of the prettiest of our smaller ornamental flowering trees or large shrubs. The several species bloom in the Spring and are so beautiful when in flower that they certainly deserve the names, Snowdrop and Silver Bell, which aptly describe them when displaying their white bell-shaped blooms.

Halesia tetraptera grows wild in Virginia and is the most commonly seen *Halesia*. This species is hardy as far north as New York, and in Connecticut along the sea coast. Grown as a tree, it reaches in time a height of twenty to thirty feet, and a few trees in old gardens have reached a height of forty feet.

Another species, *H. diptera*, a native of the Carolinas and southward, thrives as far north as Philadelphia, blooming about two weeks later than *H. tetraptera*, which

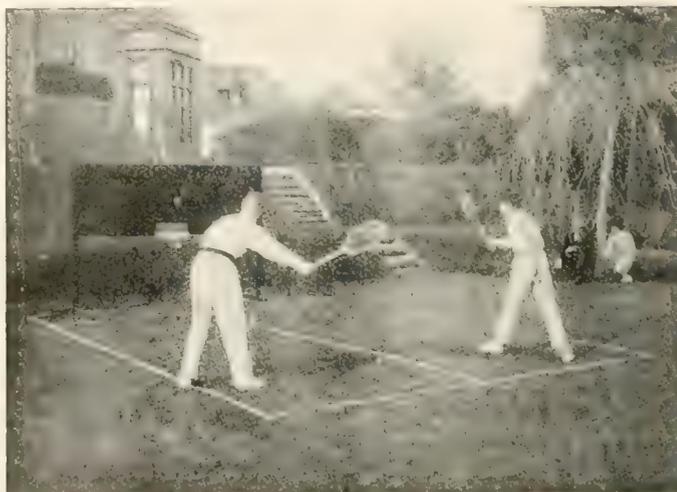

makes it desirable to plant with the latter species where the climate permits, as the two afford a succession of beautiful flowers in Spring.

Halesia Meehania, perhaps hybrid, is very distinct from *H. tetraptera* and *diptera*, both in its habit of growth, which is more bushy and less rampant, and its smaller and more clustered leaves and smaller flowers. This, as well as the other mentioned species of *Halesia*, has the gratifying habit of beginning to flower when only a few feet high, and of growing into a small tree, if it is so desired, when confined to a single stem.

There is a truly beautiful little tree from Japan, introduced into catalogs as *Pterostyrax hispidum*, which botanists say is a *Halesia*, though its flowers look very different. They appear in Wisteria-like racemes and show well in late May amid large leaves. As this tree has a spreading habit of growth, it makes a fine shade tree.

FIVE-TEN TENNIS FOR THE SMALL LAWN

THE new game of Five-Ten which has recently come out is an excellent substitute for lawn tennis where the garden is not sufficiently large for a full-sized court. It is excellent practice for tennis, and can be played and enjoyed by one player—and the space required varies from one-half to one-sixth of the area of a tennis court, which means that it can—if required—be played even in a large room.

(Courtesy of *Gardening Illustrated*)

Five-Ten Tennis Court on Small Lawn

The apparatus is inexpensive, and consists of a frame, the upper part of which is wood and the lower netting—the height of a tennis net. In the centre of the frame, above the netting, is a gap, three feet above the ground, with a pocket to receive the ball. The minimum size of the court is seven yards by three and one-half yards, and the maximum twelve yards by seven yards. The service is played from the base line, and the object is to serve the ball into the pocket. If successful this scores a point; if missed and the ball rebounds from the board it acts the same as in tennis, and is received by the opponent, and is followed up by each player alternately until it is placed into the pocket, hits the net, or goes out of bounds. In the first case it counts a point to the striker, and in the two latter against the striker.

It is an excellent game and requires skill and accuracy, and affords splendid practice for stroke play for tennis—both for back and fore hand—and improves the eye.

Those people who are looking out for a really good garden game should see Five-Ten played, and I think they will come to the conclusion that they have found the thing they want. *Gardening Illustrated*.

Some New Hardy Plant Introductions

ARTHUR SMITH

DURING recent years no part of the world has been more fruitful in worth-while plant discoveries than western and northern China; worth-while by reason of the fact that the climatic conditions of that region render its flora to be for the most part capable of making itself at home in the more northern districts of America and of Europe.

Among the newest of these plants is *Clematis tangutica obtusiuscula* introduced into Britain from China by Farrer by means of seed. Plants from these seeds arrived at the seed-producing stage themselves several years ago, and it has been of course very easy for plants to be produced in America by the same means.

This *Clematis* is especially noteworthy on account of its, for the genus, unique floral characters, its flowers being of a yellow color and bell-shaped. While yellow is not unknown among other species of Chinese *clematis*, as several different ones have been sent to Britain during recent years, the species mentioned is distinctly the best.

The first yellow-flowered *Clematis* was introduced into Europe from northern China in the year 1731, but did not come into general cultivation. *Clematis tangutica*, a native of central Asia, was introduced into Kew in 1898, and figures in the "Botanical Magazine" 7710 under the name of *C. orientalis* var. *tangutica*; this is now classed as a separate species.

Seeds of the variety known as *obtusiuscula*, which is the subject of this note, were subsequently sent to Britain by Wilson, Purdon and Farrer from Kansu and Szechwan, and the resulting plants have proved in every way superior to the type. At the Royal Horticultural Gardens, Wisley, it has proved a vigorous grower, bearing from July onwards, as Farrer describes it, "innumerable blossoms that hang in a mass like big Fritillaries of pure unchecked gold." The flowers, about four inches across, are borne singly upon stiff stalks five inches long, and later in the year they turn into a beautiful mass of snowy silk. While plants from seed begin to flower at an early age, my seedlings have not yet reached that stage.

Incidentally it may be mentioned that this plant frequently bears a second crop of flowers in September. From all points of view it is a decided and valuable acquisition among our climbing plants.

One sometimes hears the well known hardy *Buddleia* of our gardens, *Buddleia variabilis magnifica*, complained of as being coarse and ugly in its manner of growth. This characteristic can, however, be easily remedied by proper pruning; in fact, Nature frequently performs this operation when in exceptionally severe Winters the plant is killed to the ground, although we have never known it killed outright.

During his botanical explorations in China, a few years ago, Farrer discovered many forms of *B. variabilis* in the Kwantung district, and in the Nan-Ho valley he found a form with smaller leaves and larger flower-spikes, and he speaks of it as "growing especially neat and small, dainty-leaved and brilliant," so he sent home seeds of it in the hope that the form would prove constant. The plants raised at Wisley from these seeds have adhered to Farrer's description, the difference in height, etc., being apparently constant, and its habit is somewhat similar to *B. Veitchiana* with erect arching branches on a smaller scale, so that it forms a neat, round bush about three and a half feet tall, and its lacking of the coarse, sprawling habit, especially if uncared for, of *B. variabilis magnifica*, undoubtedly makes it an acquisition to our gardens, par-

ticularly in small ones. This plant has been named *B. variabilis nanhoensis*. Like all members of the genus it should have its previous year's growth hard pruned. I am not aware how soon it blooms from seed, but seedlings grow rapidly and am expecting to have plants in bloom this year from seeds sown late this Spring.

I am trying out some new *Berberis*, of which *B. aggregata*, not hitherto, I believe known in America, bids fair to have unique foliage characteristics; also a new *Pyracantha*, these and others will be fully described in a future issue.

Obviously there is nothing in the regulations of the F. H. B. which prevent the introduction of new—or old for that matter—species of worth-while plants.

THE NOMENCLATURE OF GARDEN VARIETIES

THE bewildering host of names attached to the varietal forms of garden plants and vegetables is becoming an increasing source of vexation to the gardener who tries to maintain an up-to-date knowledge of modern horticulture. But nobody would attempt to find fault with the increase of the number of varieties, provided these had definite claims to being distinct from those which had preceded them. It is obviously disappointing to buy seeds of a so-called novelty which, when grown, proves to be too similar to another sort to warrant a different name. It is still more vexing to grow a supposed new variety which proves to be nothing but an old and familiar sort. Of course, in many cases the production and putting into commerce of spurious novelties are purely accidental. The raiser is unaware of the existence of a variety which his imagined novelty so closely resembles. At other times, however, the distributor of the spurious novelty has been induced to re-christen an old sort for the sake of the increased price which is usually asked for a new production. One refrains from excess of criticism in either case. In the first instance the error is due to ignorance, while even in the second case one may sometimes find reason for justification. It is possible that the raiser may have grown a particularly fine strain of a certain type, and in his somewhat pardonable pride he considers his production worthy of a new name. But he is apt to overlook the fact that others, too, may raise equally fine strains, and if each raiser assumed the responsibility of re-naming such varieties it is easy to see the amount of complexity which is bound to arise. The only legitimate course, therefore, is for the raiser to adhere to the original type name and prefix the word "improved" with his own name attached. The purchaser would then know what he was paying for, and if he chose to pay a little more for Smith's Improved this or Jones's Selected that, so much the better for both the raiser and grower. This, of course, is done by most of the big seed houses, and the public know where they are.

Most readers will agree with the suggestion that the indiscriminate introduction of flower and vegetable novelties is not in the best interests of horticulture. There are thousands of gardeners who are always ready to lay out a little money each year on new introductions, but if these willing purchasers have been induced to buy so-called novelties, which are new in name only, they will lose faith, and the many introducers of genuine new types will suffer in consequence.—*Gardening Illustrated*.

Use and Arrangement of Bearded Irises

THE choice of position in the garden for Bearded Irises is a matter that depends to a very great extent on the garden. It would be absurd to attempt to devote a portion of a small or even a moderate-sized garden to Irises exclusively. It is also unnecessary. Where space permits it is a very excellent arrangement for many reasons, but it must be remembered that, wonderful as is the range of color and diversity of form, the flowering period is restricted to certain months in the year, and that when out of flower they are no more attractive than many other plants that are just as indispensable.

In gardens where space is limited there are two positions in which they can be used successfully. One is in the vacant spaces that always occur in the front of shrubbery plantings. Bold masses planted in such positions are always attractive during the flowering period, and even when there are no flowers the sword-like green or gray foliage adds a useful note to the shrubbery. Used in association with flowering shrubs they are most effective.

But whether the shrubs are evergreen or deciduous flowering, the introduction of Irises among them will always produce some wonderful effects.

The colors of the Irises have to be rightly chosen, and either contrast or harmony can be achieved. There are, for instance, some evergreen shrubs with cool gray foliage at Iris-time. With these as a background it is impossible to go wrong. The violet and blue shades of the Irises will melt softly into the tone of the shrubs, or the warmer-colored forms light up to more vivid splendor by virtue of the contrast with the coldness of the shrubs' tones. Wistarias grown as bush specimens also associate well with Irises.

Some gardens are too small to have room even for a shrubbery that offers much opportunity for this sort of treatment, but few are so small that they cannot afford space for them in the herbaceous border. Nor is there any place in the garden more suitable for them, and startlingly beautiful effects can be obtained by associating them with other perennial plants in this way. A May or June border in which are planted groups of Irises in positions in which they borrow from some plants or lend to others some charm of combination is by far the happiest result that can be achieved throughout the garden year. Years ago, it was discovered that one of the best plant combinations was Lupins and Irises. Since then both plants have progressed enormously in the color range offered to the gardener. For some time it has been truthfully asserted that there is no other genus that has the color wealth of the modern Bearded Iris, and now hybridists offer us Lupins of innumerable intermediate shades ranging from pure white to black purple and maroon, through every shade of pink, blue, violet, cream, buff, orange and even crimson. Here, then, is a wealth of color large enough to meet the most exhaustive demands that may be made on it, and the garden-lover who cannot have his or her heart's desire in color combination with them, lacks the knowledge to choose the right material.

It is all very well for some very good gardeners, both amateur and professional, to scoff as they do at what they call "color fads in the garden." True, sometimes this color arrangement is carried to extremes, and where harmony is aimed at monotony is often achieved. I have heard it argued that Nature never groups her colors. Nor does she. Nature makes no attempt to harmonize the music of the woodland, such as the warbling of birds and the sound of falling water. But in music the sounds are arranged, and in good painting the crude color is rejected

and softened to fine harmony. All sound and all color is of Nature, and it is only its selection and arrangement that makes art. The very essence of good gardening is that it selects, civilizes and arranges.

So in planting the Bearded Irises, if by care in color association the true value of the plants can be emphasized, the delicacy of tone of some brought out, the vivid richness of others strengthened, this is assuredly desirable.

In the herbaceous border every group of Irises should form a selected picture. The potential variety of color grouping is so great that it is impossible to particularize in the present article, and in any case the selections for color grouping must be left to individual desire. A group of dark purple Lupins will suggest to some a splash of the brighter golden yellow Irises, to others a grouping of the amber, bronze and copper tones. A group of pale yellow Lupins will likewise produce in some a desire for the combination of rose shades of Irises, in others the richest of violets. The brighter, bluest violets of the Irises are not good when planted in association with the bluest of the Lupins.

In the larger garden, wherever it is possible, the finest results of all are obtained by devoting a portion to the cultivation of Irises primarily, just as one does for Roses. Gently undulating land, grassy paths winding between banks of the glowing tints and exquisite forms of the modern Irises, offer a realm of endeavor well worthy of the most enthusiastic exploration. Informality in arrangement is preferable and color grouping desirable, and this is easy now that most catalogs divide the Irises up into color groups and state height and time of flowering.

One word of warning. There is a tendency to plant all sorts of things in grass. "Naturalizing" it is called, and some very charming effects are obtained in this way when the right material is used. Do not, however, do it with the Bearded Irises. It is not naturalizing them but murdering them. They will not stand it, and if they are to succeed the grass must be kept clear of their roots. So long as the grass of the path is kept even a few inches away they are happy. Another warning is, do not plant them in dense shade and expect them to do more than grow foliage luxuriantly for a time. To flower they must have sunshine, and the more they get the better they like it. *The Garden.*

THINGS AND THOUGHTS OF THE GARDEN

(Continued from page 192)

ber. I have used Achimenes in the same way and they have flowered for months. Passers by would ejaculate, "Look at the lovely baskets of petunias!" Petunias are good basket plants, so are the trailing forms of blue lobelias, while nothing could be finer than the ivy leaved geraniums, especially the pink ones. These are not the only flowering plants available by any means, but they include some of the better known sorts. Given a generous soil and plenty of water, basket plants are a great asset for use not alone in the greenhouse, but in pergolas, piazzas, and porches. Anyone who has tried one or two will want more the following year. With window boxes and hanging baskets a very sombre looking home can be wonderfully beautified. There are a number of foliage plants well adapted for basket culture, amongst which are English ivy, Kenilworth ivy (which is fine grown with fuchsias), Asparagus Sprengeri, Coprosma Baueriana, Tradescantia, green and variegated Vincas.

Foreign Exchange Department

A ROSE WITHOUT A RIVAL!—HIAWATHA.—It may appear presumptuous to say of any particular Rose that it is without a rival, or even to claim for it some distinguishing characteristic over others, in these days when there are so many beautiful varieties, but beauty is fleeting and the fairest Rose of the morning has often lost much of its charm by noon! Hiawatha (a single sort, too!) is different from any other. Of that there is no shadow of doubt, and its very remarkable trait is the longevity of its blossoms. As we know, who grow it, it yields numerous crimson clusters with golden anthers and, when the latter fall, there is revealed a white centre to the petals which rather increases their attraction than otherwise. It is these clusters so lavishly produced which often in a hot season will last three or four weeks before the petals fall, while in a normal season they will continue in beauty longer than this. As a grower of Hiawatha from the time of its introduction I know of no other Rose for which one can prefer a similar claim and, certainly, there is no variety that is better adapted for clothing with flowers for the longest possible time an arch or pergola. Its staying power is unique.—*The Garden.*

ORIENTAL POPPY MOGUL.—So far as size goes, Mogul appears to be the finest of the scarlet smooth-edged Oriental Poppies of the present day. It was well exhibited at the last Chelsea Show, and appears destined to meet with much favor from those who appreciate these noble Oriental Poppies, which are nowadays such a conspicuous feature of the June flower garden. Looking back on the time when we had only the ordinary orange-scarlet typical *Papaver orientale* and that fine one, still in favor, *P. orientale bracteatum*, it is amazing the advance made in these flowers and the increasing popularity they have gained. Mogul deserves to be remembered when planting time comes round.—*Gardening Illustrated.*

CALIFORNIA BLUE BELL (NEMOPHILA MENZIESII).—By far the most beautiful of the family is the above, a bed of which is one of the most lovely features of the garden at the present time, and this in spite of a wealth of other lovely alpine flowers also in bloom. The seeds were sown in their present position in September last, as this is by far the most satisfactory method of treating this exquisite annual. The flowers are of the most exquisite sky-blue, with a white centre, and each one and one-half inches across, the bed containing them resembling a carpet of blue from a distance. Many have been the admirers of this little flower during the past few weeks, and yet it is one so easily obtained if only gardeners would sow the seed in Autumn on well-drained soil instead of in the Spring, for if sown at the latter time the effect cannot be compared with that of plants sown in Autumn. There is a fine selected strain, known as *grandiflora*, with larger blooms and a very charming white form, also a claret-colored one, *purpurea rubra*, but the beauty of the above is unsurpassed.—*Gardening Illustrated.*

THE WHITE-HORNED VIOLET (VIOLA CORNUTA ALBA).—Very pretty is this free-flowering plant as it clothes the face of a low wall with its pure white flowers. Although this lovely kind is not so often seen as the mauve and purple kinds, it is equally effective and just as easy to grow, coming true from seeds. Unlike many of the Tufted Pansies, it does not appear to be so easily affected during periods of drought. Of perennial character, this plant makes fine broad edgings and groups, and, being free in growth, may be increased to any extent, either in Autumn or Spring.—*Gardening Illustrated.*

THE RIGHT RESULTS IN FLOWERS.—No nation shows more artistry in flowers than do the Japanese, and they secure their lovely effects with the least expenditure of material. See them arrange a couple of sprays of Flowering Cherries in a plain vase, and what a delight it is; whereas a massed pot soon wearies. How do they attain to it?—By study of Nature's methods, and learning the harmony of colors. It takes time, but the results are worth it.

In contrast, consider the average arrangement of flowers in most homes: Crude bunches of assorted blooms, in vases or surroundings which positively cry aloud from the outrage of clashing color or redundant grouping. A few pointers may be acceptable—

Small flowers for a small room.

In a flowered vase, flowers create an anti-climax.

To place flowers in front of a picture, is unfair to the flowers and unfortunate for the picture.

Think of your walls not as something to be hid but rather as backgrounds for appropriate color.

In arrangement, remember Nature and not the massed bloom of an ordinary Florist Shop.—*S. African Gardening and Country Life.*

THE OPENING AND CLOSING OF WATER LILIES.—Investigations in the past and again recently on the opening and closing of Water Lily flowers show that it is due to the action of sunlight, and the absence of sunlight respectively. The common white Water Lily opens at 5 A. M. at Upsala, Sweden, but not until between 7 A. M. and 8 A. M. at Innsbruck, Austria; and in both cases this coincides with the shining of the rising sun upon them. The flowers close at 5 P. M. at Upsala, and between 7 P. M. and 8 P. M. at Innsbruck. This is due to the fact that the sun rises earlier at Upsala than at Innsbruck, during the flowering season. The flowers never open at exhibitions unless the sun shines upon them, though the exhibitors may be expert growers. If the flowers are cut while open they can certainly be enjoyed for a time, but they should be as fully exposed to sunshine as circumstances permit. Tepid water might delay their closing towards the end of the day.—*The Garden.*

PRIMULA SIKKIMENSIS.—I often wonder why more people do not grow the Sikkim Cowslip (*Primula sikkimensis*). Perhaps the reason is that it is not always a long-lived plant. It seeds very freely, and it is easy to raise seedlings. It is best to sow the seeds as soon as ripe, but it is not always safe to do this in the open ground. I put the seeds in sandy soil in a pot in a frame, where they remain plunged in ashes during Winter. In Spring a good many young plants appear, but I leave the pot untouched, except that I pick out the little seedlings which have appeared when they have made a pair of their second or true leaves. By leaving the pots for another Spring I get an additional number of seedlings, as the seeds do not always germinate the first year, although a bigger proportion does if they are sown as soon as they are ripe.—*Gardening Illustrated.*

CLIVIA MINIATA.—The merits of the Clivia as a handsome-foliaged and flowering plant are by no means so fully recognized as they should be, particularly by the amateur with but a single greenhouse, for it is by no means difficult to cultivate, and is effective at all seasons. When in good condition the long strap-shaped leaves are of a particularly rich green tint, and when they are well overtopped by a rounded head of blossoms a large specimen forms a most imposing feature. It is also a good window plant, and may be kept in health for a long time in a dwelling-house.

The soil best suited for the different Clivias should consist mainly of good yellow loam, lightened by an admixture of sand, nodules of charcoal, and leaf-mould. The best time to repot is immediately the flowers are past, and in carrying this out it is very essential that the pots be clean and well drained. After potting, the plants should be kept in the greenhouse, giving them a good light position. When the pots are well filled with roots, water may be liberally supplied, while overhead syringing is, in the height of Summer, very beneficial. In Winter much less water should be given, as in this way the plants get a partial rest. When large they can be kept in health for years without repotting, in which case they are greatly assisted by an occasional watering with weak cow-manure and soot-water mixed, taking care that it is quite clear, as if at all thick it is apt to clog up the drainage and the plant will then soon fall into ill-health.—*Gardening Illustrated.*

A USEFUL ANTIRRHINUM FOR WALLS.—The homely and old-fashioned Snapdragons, varieties of *Antirrhinum majus*, are so well known—indeed, so universally popular that they need no word of description or recommendation. However, *Antirrhinum asarina* is quite a different plant, and is a very charming little thing that deserves to be much grown where conditions are favorable to its well-being. Some of the healthiest and most floriferous plants I have seen were growing on the face of an old stone wall, a position which was evidently exactly to their liking. Being of trailing habit, the stems hung down over the stones, draping them with festoons of soft green, woolly foliage, and for the greater part of the Summer goodly numbers of comparatively large creamy flowers with yellow throat were to be found pushing up between the leaves. The latter bear but little resemblance to the *Antirrhinum* generally grown; indeed, it might almost be mistaken for some hoary-leaved *Campanula*, but the flower is quite of the familiar Snapdragon form. In addition to positions on walls, this plant is well adapted to cultivation in fairly dry pockets on the rockery, and in shallow pans it makes a very effective plant. It is not sufficiently hardy to withstand full exposure in bleak windswept spots, neither will it survive where the soil is surcharged with stagnant water, but in sheltered, well drained places it will do well. A point in its favor is that seeds germinate freely, and the young seedlings quickly attain to flowering size.—*The Garden.*

THE ROCKETS.—If one has a love for a really beautiful and showy old-world flower one should grow the Rocket, *Hesperis matronalis*, which is deliciously scented, especially in the evening.

and it remains pink in color over an extended period. This is a hardy perennial, varying in color from pink and purple to red, reddish purple and white. There are both single and double forms, the double white being grand. All varieties, in addition to their imposing appearance in the borders, are splendid for cutting and reach a height of about a yard. Propagation of the single forms can be effected without the least difficulty by seeds sown in Spring, but the most satisfactory way of increasing fine forms is by division. This should be done in July or August by lifting the entire clump and splitting it up into single pieces, which are then at once replanted either in the reserve garden or their permanent positions. Where one has a stock of established plants, these can safely be transplanted either in Spring or Autumn. To increase the splendid double sorts, such as the Scotch and French varieties, the easiest method is to strike cuttings. These can be obtained from the parent plants about the middle of June, and should be trimmed clean of the larger leaves at the base and immediately inserted in a bed of light gritty earth in a cold frame. Avoid overwatering, but keep moist at roots and rather close for a week or two. Light overhead sprinklings are a great assistance in keeping the foliage fresh until roots form. Once roots are formed the frame can be lifted off so as to expose the plants fully to air and sunshine. Early in Autumn the plants may be placed in their permanent quarters.—*The Garden*.

SWEET ROCKET IN THE GRASS.—I grow a good number of the single-flowered Sweet Rocket, as it is so useful for cut bloom, but until this season I was not aware that it would thrive in the grass. The finest specimen I have ever had is growing among quite rank grass and is self-sown. Therefore, this Rocket is evidently one of those things that can easily be naturalized in the wild garden and woodland. A few plants set out in the Autumn would, perhaps, be the easiest way, for my experience is that if this Rocket is allowed to form and shed its seeds every year young plants will spring up, and these self-sown plants invariably make strong growth and bloom profusely. A colony of this Rocket is very attractive, as the flowers vary in color from almost white through shades of pink to almost crimson.—*Garden-illustrated*.

RANUNCULUS ACONITIFOLIUS.—Though an old plant, this is not seen in gardens as often as it might be, for it is of the easiest culture in any fairly good border soil that is not too dry, and it is as beautiful in foliage as it is in flower. An herbaceous species, it appears in early Spring and makes a bold clump some eighteen inches high of ruddy, angular stems and smooth, deeply divided leaves. These are followed by a galaxy of white blossoms about one inch across of remarkable purity and elegance. There is a double form, our old friend "Fair Maids of France," or Bachelor's Buttons, in which the blossoms are each congested into tight little wads of white, which are not comparable to those of the type where beauty of form is a consideration, though they may last longer. This double variety is, nevertheless, the one more commonly seen in cultivation.—*The Garden*.

THE CULT OF THE ZINNIA.—To those unaccustomed to Zinnias, disappointment sometimes dogs their footsteps when growing them for the first time. To the uninitiated they are somewhat of an enigma, an annual which gives one the impression that they are robust, when, in reality, they are not; and if planted out too soon are frequently retarded. They love a rich, light soil, and above all a sunny position. I have found they do best when planted out on a wall border having a south aspect. In the Summer of 1921, with its weeks of drought, Zinnias held their own and bloomed more freely than many other annuals, some of which succumbed. Most people are anxious to complete their garden arrangements before May is out, but one has to remember that it is a month, not infrequently, of extremes of temperature and unless quarters similar to those described can be selected for the plants, it is better to allow them to remain in frames a week or two longer. Zinnias continue in bloom longer possibly than any other annual, so that it is unwise to hurry them out of doors before genial weather conditions prevail.—*The Garden*.

Brief Horticultural Jottings

As the first of the new year part of Spring may well remember that, unless the powers behind Quarantine 37 change their minds, this innocent bulb is to be forbidden in three years. You can't imagine Spring without its hosts of daffodils dancing in the breeze? The pest hounds at Washington can. If they could, they would forbid the breeze because it carries spores of plant disease. The pest hounds at Washington can. How that is a season when pests awaken to their nefarious work! How-

ever, this is the cloud—no bigger than a pest hound's hand—that presages the coming storm. In these three years we must stock our gardens. After that the narcissus will join whiskey and be forbidden these shores. Perhaps the day will come when bulb-leggers from Holland will anchor outside the three-mile limit and garden lovers in small boats will sneak out under cover of night to buy their share of Spring glory.—*House & Garden*.

The Cambridge Botanic Garden, England, recently celebrated its three hundredth year for it was started on July 25, 1622. A number of notables gathered at the garden to celebrate the tercentenary of this famous institution, which while not large, has played a big part in the development of horticulture. In 1637 it contained some 3,000 species. Morison's History of Plants was partly written by Prof. R. Morison, an early curator, while he was in charge of this garden and completed after his death by J. Bobart, who succeeded him.—*Florists' Exchange*.

The army of flowers is at last assaulting the unsightly places of the national capital. George W. Hess, director of the Botanic Garden, is the leader of this peaceful army and is the moving spirit in the effort to get appropriations from Congress for the extension and modernization of the garden. President Washington had a project for a botanical garden in 1796, but took no action in the matter. The history of the Botanic Garden since Washington's time is a story of half-hearted support by Congress and half-way successes of some non-governmental bodies and movements to interest the citizenry.

After Mr. Hess had aroused the enthusiasm of a number of Senators and Representatives who had authority in the affairs of the garden, legislative approval was secured. The proposal was submitted in detail to the fine arts commission, where it received cordial approbation. On a triangular plot, south of the propagating gardens, a show house, 45 x 112 feet, is to be erected. Beyond this triangle, a crescent-shaped strip of land, part of which is used for the storage of junk, discarded vehicles and similar undecorative objects, will give way to Mr. Hess' plan for beautification. When Congress meets again an appropriation, probably of \$800,000, will be asked.—*Florist Review*.

At North Church, N. J., the Board of Freeholders is making a fight to save the 300-year-old Oak, which, according to the authorities, is impeding the motor traffic. It stands almost in the center of the highway and orders have been given to a contractor to remove it, although one property owner has offered land, so that the road can be diverted. The tree sheltered George Washington and is said to bear visible traces of the message of victory he carved upon it. The removal of the tree was ordered because motorists declare it to be a menace.—*Exchange*.

Comments from Our Readers

On reading July's number of the CHRONICLE, of which I am a keen follower, both for its interesting and helpful articles, I came across the section headed, "Comments from Our Readers," emphasizing the fact that cultural notes, etc., were encouraged and specially dedicated to the young class of gardeners. Therefore, I am venturing on my first attempt, hoping that my boldness will stimulate others who are more adept. I am employed as assistant gardener. Having charge of the "Kitchen Garden" and being instructed that the owner was specially fond of obtaining head lettuce regardless of season or climatic conditions, I set forth to try my best, which led me to different experiments. The one that I am enclosing has proved a success and I am sure is worthy of consideration and trial.

West End, New Jersey.

FREDERIC HEUTTE.

(Mr. Heutte's remarks on heading lettuce appear on page 212.—*Editor*.)

Mr. Craig's note in the last issue of the CHRONICLE, on the tendency of certain Tulips to throw more than one flower to the bulb, reminded me of an unusually fine specimen of the Darwin variety, "Farncombe Sanders," which occurred in a planting I made a few years ago. This bulb produced five flowers—four from the center of the bulb and one, the smallest, from an offset. What would our bulb-growing friends not give to be able to produce any quantity of bulbs having this multiflorous character well fixed. The flowering stem of the variety "Philippe de Commines" frequently divides about half way and bears twin flowers, equally as good as any borne singly. Other unusual features I have noted in Tulips have been the occasional production of a bulblet on the flower stem and flowers having eight petals, eight stamens and four pistils.

Parthenon, N. Y.

H. F. DOWNER.

National Association Of Gardeners

Secretary's Office, 286 Fifth Ave., New York

1923 Convention, Pittsburgh, Pa., August 14, 15, 16, 17.

The aims of the association are to elevate the profession of gardening by improving conditions within it.—To cement a closer bondship among all engaged in, and interested in, gardening—to create a greater confidence between employer and employee.

Co-operating with the Massachusetts Agricultural College, the association conducts a course in training young men for the profession, whereby they obtain theoretical knowledge as well as practical experience.

OFFICERS 1923

President JOHN BARNET, <i>Sewickley, Pa.</i>	Vice-President ROBERT P. BRYDON, <i>Cleveland, O.</i>
Secretary M. C. EBEL, <i>New York, N. Y.</i>	Treasurer MONTAGUE FREE, <i>Brooklyn, N. Y.</i>

TRUSTEES (For 1923)—Thomas W. Head, D. L. Mackintosh, Arthur Smith, New Jersey; Robert Cameron, Massachusetts; Andrew L. Dorward, Rhode Island.

DIRECTORS—(To serve until 1924) William Hertrick, California; George H. Pring, Missouri; Robert Weeks, Ohio; Thomas Wilson, New York; Harold Bryant, Connecticut; Harry Cartwright, Michigan; H. Ernest Downer, New York. (To serve until 1925) George Wilson, Illinois; James Stuart, New York; William Kleinheinz, Pennsylvania; Edwin Jenkins, Massachusetts; Carl N. Fohn, Colorado; Joseph Tansey, New York; John Tonkin, Pennsylvania. (To serve until 1926) Alexander Michie, New York; George F. Stewart, Massachusetts; Theodore Wirth, Minnesota; George W. Hess, District of Columbia; R. P. Brydon, Ohio; William C. Rust, Massachusetts; Charles Schroll, Wisconsin.

NORTH SHORE OF ILLINOIS: James A. Wilson, Lake Forest, chairman; John R. Clarke, Glenoco, secretary.

THE ANNUAL CONVENTION

As the August number of the GARDENERS' CHRONICLE goes to press, the members of the National Association of Gardeners are gathering in Pittsburgh for their annual convention to be held at the Fort Pitt Hotel, August 14, 15, 16, 17. To have awaited the report of the proceedings of the meetings for this number would have delayed publication too long, so that they must be withheld until the September issue.

We have, however, secured a copy of the President's address and the Secretary's report which are being published in this issue.

Late reports from Pittsburgh indicate that the convention will be a most successful one with a large attendance of members from different parts of the country, and with the local members well prepared to provide for the comfort and enjoyment of the visitors.

THE PRESIDENT'S ADDRESS

It is indeed a great pleasure for me to welcome you on behalf of the National Association of Gardeners to the "Smoky City." Again we meet in convention to review what has been accomplished during the past year and to make plans for the year to come. Many more, I am sure, would be with us were it at all possible for them to get away. Assistant gardeners are almost unprocureable, and day labor is beyond reach for our work, because business is such that wages are being paid far beyond what many owners of private estates are prepared to pay.

Let us hope that 1924 will be better. I believe that we ought to be optimistic, especially since we now have visions of the young men entering the profession through the training offered by some State colleges. These young men will be able to relieve gardeners and superintendents for short periods at least while they are preparing to fill our places eventually. The talk of low salaries being offered is fast diminishing, and rightly so, thanks to the efforts of the National Association of Gardeners. I think that the time is not far distant when gardeners' salaries will compare favorably with any of the other professions. What is needed is publicity of some kind that will set forth the advantages to be obtained by being employed in such healthful occupation; the satisfaction of achieving something through contact with Nature; and the compensations received which cannot be measured in dollars and cents.

Honesty and fearlessness for the right will always be rewarded, and while there are employers who are not above being suspicious, it is to be regretted in many cases that they have been made that way by many of the so-called gardeners, whom, I am pleased to say, the National Association of Gardeners has and will continue to bring to light as time goes on.

It has been my good fortune to hold office during the inauguration of the course at the Massachusetts Agricultural College in co-operation with the national association. While the number of students was not all that was hoped for, the coming term holds forth greater promise. It might be of interest at this time to announce that the Pennsylvania State College has acquired by the will of a wealthy resident of the State a fine estate, comprising some two hundred acres, which will be at the disposal of the faculty for horticultural training. They are willing, I understand, to co-operate with the National Association of Gardeners along the lines of the Massachusetts Agricultural College. When this subject comes up for discussion at our business session, I hope you will give it your earnest consideration and that a workable solution may be derived.

An unfortunate incident occurred during the present administration when the integrity of the gardener and his profession was attacked, but the association ably defended the cause for which it stands (thanks to our worthy secretary) which created a closer fellowship between the local gardeners' organizations and the national association, for practically all local organizations east of the Mississippi and some west of it passed resolutions endorsing the action of the national body. Let us at all times be ready to guard zealously the interest of our association and what it represents, whether it be the individual's, association's or the press, strike out for the right without hesitation. I might call attention at this point to the fact that while the officers of the association are ready and willing at all times to do their full share, without the co-operation of the members at large, they are handicapped in their efforts to advance the cause of the profession, and that this lack of co-operation is not always due to an unwillingness on the part of the members to do their part, but rather to the inclination to "pass it along to Sweeney."

The secretary's report will show that while we have lost some members during the year, the new members acquired will offset the loss, and the membership has therefore not diminished. It is to be regretted, however, that more members have not induced their employers to become sustaining members. The events at New York, Boston and Pittsburgh clearly illustrate how much interest estate owners have in the gardeners' national association. To those who contemplate doing so, I suggest that they emphasize the point that our association is by no means a labor union in any sense of the word, but a means to an end whereby gardeners of the proper training can secure better positions and employers obtain the services of better gardeners.

I am pleased to draw your attention to the interest being manifested in the local branches. It is not so long since we had only one; last year we had five, and before the end of the year that number will be doubled. There is no doubt in my mind that if we are to advance for good, it has to come through the local branches. We may have to amend our Constitution and By-Laws, but that surely is permissible in an association such as ours.

... we met in this last year, outside of the important business to be transacted, it was to be expected that we should see some of the most and best places in the country. But in Pittsburgh, otherwise known as the "Work-shop of the World," we cannot begin to boast of things horticulturally, though what you will see is creditable indeed, when the effort, which must be spent under somewhat adverse conditions, is considered. Industrially, you may see and judge for yourselves, referring to the "Work-shop of the World." I may be pardoned for repeating, for I am sure it will be of interest to many from a distance, some of whom may look with scorn upon the smoke, but let it be clearly understood, that when we have no smoke, we have no business. Pittsburgh leads the world in the manufacture of iron, steel, glass, electric machinery, tin plates, air-brakes, fire bricks, white leads, cork and aluminum, pickles and preserves. Pittsburgh products have an annual tonnage two and a half times greater than New York, London and Hamburg combined. The value of Pittsburgh's manufactures is two and a half billion dollars a year, which exceeds that of each of forty States. Pittsburgh is the center of a county whose assessed valuation is greater than that of each of thirty-six States in the Union. Pittsburgh has labor pay-rolls of two and a half million dollars a day. Pittsburgh's banking surplus is one hundred million dollars, and is exceeded only by New York and Philadelphia. Deposits per capita are the greatest in the United States. Sewickley, where you will visit some of our estates, is Pittsburgh's leading suburb.

I should like to say a few words in closing with a view to expressing my appreciation of the co-operation and hard work of our local committees. They have met with obstacles and disappointments but have nevertheless worked out what I consider will prove to be a very interesting, instructive and amusing convention, and while I am delighted to have the honor of welcoming you today, the credit for your enjoyment belongs to the men on the committees.

THE SECRETARY'S REPORT

The past year has been a very gratifying one for the association, in which progress has been the keynote. Interest in the activities of the association has increased on the part of gardeners' local organizations throughout the land and greater enthusiasm has been manifested among the local branches than heretofore.

The association was called on during the year to defend the morale of the gardener and his profession, due to an indiscriminate act before one of the state legislatures. While the incident attracted some publicity, it did not, however, act to the detriment of the gardener or his profession, but on the contrary, it drew attention to what the association is striving to accomplish for the profession which it represents.

A loss of seven members through death was sustained during the year, and seventeen through resignation, due to gardeners turning to other vocations where inducements appear more enticing than in their own profession. Ninety-eight active and associate members were enrolled, and nine sustaining members were also added to the association's membership.

LOCAL BRANCHES

Although the early efforts of the association to organize local branches did not meet with immediate success, the efforts put forth were not wasted as what has been accomplished this past year shows. For a long while, Newport, R. I., was the only branch in existence. This branch was followed by the St. Louis, the Nassau Co., L. I., the Boston, and the Western Pennsylvania branches. This Spring a branch was organized in Cleveland, which has since been followed by the North Shore of Illinois branch. At the present time, Jacksonville, Fla., is organizing a branch to be known as the Northern Florida branch. The members of these branches have found that at their meetings, opportunities are presented to those who are not always able to attend the conventions, to make recommendations to be submitted to the annual conventions; that assistance is assured in planning and carrying out the annual conventions; and that lively and worthwhile discussions also occur on subjects pertinent to the gardening profession, which is not possible at meetings of gardeners' local organizations where matters of purely local interest occupy the major portion of the time. It is believed that before the end of the year, other branches will be announced. As the number of branches increases, greater co-operation will develop between these branches whereby the gardeners in the different territories will come into closer fraternity.

THE SERVICE DEPARTMENT

The Service Department did not have occasion to fill many important positions this year for the reason that few such positions were offered. There, however, appeared to be more than the usual number of minor positions, many of which did not call for trained gardeners. The high cost of labor created some positions for trained men, where heretofore only handy men were engaged. The experiences have been so satisfactory that employers

report the difference in expenditure, between engaging a trained gardener and a handy man, has been well worth while. Single men have been especially benefited in this respect. However, the Service Department should not be looked upon as merely an employment bureau for its scope extends far beyond. Instances of estate owners visiting New York, some from distant points coming to the secretary's office, to discuss the problems of their estates are not unusual and have often resulted in considerable benefit to their gardeners.

ON TRAINING YOUNG MEN

There has not been as much progress made in interesting young men in taking advantage of the co-operative course offered by the Massachusetts Agricultural College and the association as might be desired, due largely to the expense that must be incurred by the young men who are non-residents of the State of Massachusetts, and who must pay tuition fees, while free tuition is granted the residents of the state. The Massachusetts Agricultural College appears satisfied with the first year's results and is looking for an increased enrollment this Fall. If other state colleges would adopt a similar course, it would prove beneficial to young men of those states who would be interested in taking up such a course. Mr. Robert Cameron, before sailing for Europe, wrote to the secretary, urging him not to overlook bringing up this important subject at the convention. He stated that he is employing four college men who are proving more than satisfactory, and that he believes the future of the young gardeners can be solved if further attention is given to their educational opportunities. Another member has written the secretary that he thinks it is just as essential to educate young men along executive lines as to educate them on the growing of plants and otherwise instruct them horticulturally. He contends that estate owners are equally interested in properly kept records and accounts as they are in well raised plants. A young man who takes a horticultural course should develop enough intelligence to be able to keep his accounts straight on the average estate. In fact, the Massachusetts Agricultural College includes business methods and English in its course, which should be sufficient to broaden the scope of a young man's mind and enable him to adapt himself to many conditions which may arise in his life's work, and with which he may not have had previous experience.

ON PROFESSIONAL ETHICS

Much stress is placed from time to time on improving professional ethics and business methods from which the horticultural trade is not excluded. The association directs attention that it was one of the first organizations, identified with horticulture, to go on record as in favor of improving professional ethics and business methods, not alone in the pursuit of horticulture but in all vocations. It passed a resolution to that effect at its annual convention held in Cleveland in 1919, and its stand remains unchanged. It may be added that the efforts of the gardening profession in recent years towards the advancement of its standard has been no less progressive than those of other professions, which can be readily confirmed by any interested investigator. Applying the Golden Rule in business, and out of it, individually and collectively, will prove the most effective remedy in curing all business ailments.

A WORD ON "RUMOR MONGERS"

The despicable practice, which is not a new one, of circulating false rumors, either through ignorance or with malicious intent, often resulting in severe hardship to the ones against whom they are directed, seems to be increasing rather than decreasing. The association during the past Spring has been called on to suppress several rumors which on investigation were found to have no foundation. The rumors usually refer to a gardener's position, that he is leaving or is being discharged, and so the employer, after he has been flooded with applications for the position, believes that there must be some truth to the report that his gardener is leaving his employ, and forthwith dismisses him without even an opportunity for an explanation.

The secretary believes that the time has arrived when the association should decide on some policy to mete out merited punishment to the "rumor monger" who maliciously injures another, whether the guilty one be an active or associate member. The By-Laws already provide power and certainly dismissal is none to be feared.

OUR DECEASED MEMBERS

Since the convention in Boston last year, the secretary's office has received notice of the passing of the following members: Sustaining, Frank J. Dupignac, Mamaroneck, N. Y.; Active, William Gray, Newport, R. I., M. J. O'Brien, Mt. Kisco, N. Y., Douglas Smith, Katonah, N. Y., E. Stuart Smith, Spring Valley, N. Y., Frank E. Ehrler, Pittsfield, Mass.; Associate, John S. Hay, Philadelphia, Pa. It is possible that there are other deceased members, of whom the association has not been informed.

OUR SUSTAINING MEMBERS

There is no doubt there are many owners of country estates who would willingly give their support to the association if invited to do so. If our active members would make an effort to interest their employers, our sustaining membership would materially increase. Estate owners who never before heard of the association are often directed to it by those who are numbered among our sustaining members.

INCREASING OUR ACTIVE MEMBERSHIP

The secretary is certain that many members would be surprised to learn of the number of gardeners, who appear never to have heard of the association, notwithstanding the publicity it has received during the past years, and how readily they become interested when approached on the subject. If each member would undertake to enroll but one new member, it would mean much towards strengthening the influence of the association in its field of endeavor.

M. C. EBEL, Secretary.

BOSTON BRANCH

Due to the unusually hot weather, there was not as large an attendance as anticipated at the Boston branch meeting, held at Horticultural Hall, Boston, on July 31. It was nevertheless an interesting one with the discussions on varied subjects lasting well over two hours. A good representation from Boston and vicinity may be expected at the Pittsburgh convention.

NASSAU CO. L. I. BRANCH

A meeting of the Nassau Co. L. I. branch was held at Oyster Bay, L. I., on July 27. A general discussion ensued on what had been accomplished by the association in the past year and satisfaction was expressed on the part of the members present, the local branch endorsing the association's action. James Andrews of Oyster Bay, L. I., was appointed a delegate from this branch to the Pittsburgh convention.

WESTERN PENNSYLVANIA BRANCH

A meeting of the Western Pennsylvania Branch and the Pittsburgh Florists' and Gardeners' Club was held in the Carnegie Library, Pittsburgh on July 17 with Manus Curran, chairman, presiding, for the purpose of discussing plans for the social evening during the convention under the auspices of the club. The following applications for membership were endorsed by the branch, Edmund Ruprecht, James Stewart, William V. Beeler, and Thomas Tyler. A letter was read from John R. Clarke of Lake Forest, Ill., requesting information on the objects of this branch, which information the secretary was instructed to give.

A meeting was also held on July 31, with Manus Curran, chairman, presiding. Detailed reports of their preparations for the convention were presented by the chairmen of the various committees. By a rising vote, Manus Curran was unanimously elected to represent this branch at the convention. The application of Mrs. Mitchell, Pittsburgh, for sustaining membership was referred to the New York office. The following applications were endorsed for membership, Sabin Bolton and Hiram A. Frishkone. Everything is in readiness for what is hoped to be a successful convention.

HENRY GOODBAND, Secretary.

CLEVELAND BRANCH

A meeting of the Cleveland branch was held at the Alhambra Restaurant, August 6, Robert Brydon, chairman, presiding. It was decided to ask for a conference to be held during the time of the National Show to be staged here in the Spring of 1924. The opinion was also expressed that a booth at the show would be advisable. Frank L. Balogh was elected as delegate for this branch to the coming convention at Pittsburgh. The applications for membership of George W. Duncan, John Buckley, and Albert P. Longland were endorsed by the branch. The next meeting will be at the Alhambra Restaurant, Euclid Ave. and 105th St. on September 4, with dinner at seven o'clock.

ARTHUR BROWN, Secretary.

NEW MEMBERS

Sustaining: G. W. Hill, White Plains, N. Y. (Sidney Tranfield, gardener); C. A. Coffin, Locust Valley, L. I. (Joe Boehler, gardener); Mrs. Louise C. Moore, Mentor, Ohio (Frank L. Balogh, gardener); Mrs. C. Douglas Green, Mamaroneck, N. Y.; Miss L. T. Morris, Philadelphia, Pa. (John Tonkin, gardener); Miss J. G. Seaman, Poughkeepsie, N. Y. (Fred Cotterell, gardener). Active: Thomas E. Tyler, James Stewart, Sabin Bolton, Pittsburgh, Pa.; William V. Beeler, Haysville, Pa.; Edmund Ruprecht, Shields, Pa.; Michael F. Salmer, Joseph K. Brower, Alfred Addor, Jacksonville Fla.; Steven Dietrich, Greenwich, Conn.; Harry F. Carter, White Plains, N. Y.; M. B. Kannooski, Grand Forks, N. D., George W. Duncan, John Buckley, Youngstown, O. Associate: Hiram A. Frishkone, Pittsburgh, Pa.; Albert P. Langland, Cleveland, O.

AMONG THE GARDENERS

Daniel Whyte, for twenty years head gardener to Winthrop Ames, North Easton, Mass., has been appointed head gardener to Samuel Appleton, "Broadmere," Marblehead, Mass.

Harry Coles, of Wellesley, Mass., succeeds Mr. Whyte as gardener to Winthrop Ames, North Easton, Mass.

Robert Weeks has resigned his position as superintendent to Charles K. King, of Mansfield, Ohio, to accept a similar position on the new estate of Guerdon S. Holden, Cleveland, Ohio.

Earl Robertson, gardener for the past four years under Robert Brydon, superintendent, on the Mrs. F. F. Prentiss estate, Cleveland, succeeds Mr. Weeks as superintendent to Charles K. King, Mansfield, Ohio.

W. H. McDonald accepted the position of gardener to Edwin McClellan, Cambridge, N. Y.

Max Aubertel has accepted the position of gardener at Manetto Hill Farm, the country estate of R. Schwarzenbach, Hicksville, L. I.

THE EDUCATIVE VALUE OF FLOWER SHOWS

The ever-increasing number of horticultural societies proves beyond doubt that gardening is one of the favorite pursuits of all classes of the community. Equally noticeable is the desire to excel in the production of flowers, fruits and vegetables, and even in shows of but modest ambitions the competition is keen. That such exhibitions possess a distinct educative value cannot be disputed. They encourage a spirit of generous emulation, they teach self-restraint to the competitors, and they point out in no uncertain fashion just how and where the exhibits of the unsuccessful competitors fall short. In exhibiting, the amateur, of course, stands upon an entirely different footing from the private gardener. The former may decide whether he will compete at any given exhibition and exactly what he will stage. The private gardener, on the other hand, must, generally speaking, obtain the consent of his employer. Some employers readily grant this permission—nay, they encourage the gardener to compete at flower shows. Others object altogether to the idea, and refuse permission—in which they are quite within their rights. They state their objections somewhat in the following way: Gardeners, if permitted to exhibit, usually make up their mind at the beginning of the season as to the classes in which they intend to compete. Having decided, they concentrate on these things, and devote more time to them than to the remainder, which have to put up with perfunctory treatment, with the result that, all over, the average is lowered. I venture to express the very strong opinion that this is quite a mistaken idea. Granted that here and there a gardener may devote all his energies to the production of a limited number of subjects for competition, yet the majority will bear me out when I say, without fear of contradiction, that when a gardener is encouraged to exhibit the tendency is towards a leveling upward all round. No real gardener could tolerate a magnificent bed of onions, grown for show purposes, and a mediocre or indifferent crop of peas or cauliflowers. Similarly with flowers. Carefully thinned, shaded and staked, carnations or dahlias for exhibition would be a striking commentary on a poor or weed-infested flower garden; while a few giant gooseberries grown for the show bench would ill repay a general crop decimated by mildew or devoured by caterpillar. My experience—a tolerably wide experience—is to the effect that where the gardener, professional or amateur, is a keen exhibitor there will be found all-round crops of superior quality. As has been already said, the educative value of exhibitions is great, for gardeners, by comparing their own produce at shows with that of their competitors, are enabled to locate and to remedy faults in their treatment. The interchange of opinions, too, and the friendly criticisms which are passed at flower shows, also add to the knowledge of the exhibitor. Look at the whole question of exhibiting from any angle, and the conclusion forced upon the observer is that, from an educative point of view, the modern horticultural society is doing good work, work which is not appraised at nearly its proper value even by some of those who profess to be devoted to, and deeply interested in, the advance of horticulture.—*Gardening Illustrated*.

Owners of Country Estates

Resolving the services of gardeners thoroughly versed in all phases of their profession and qualified to assume the responsibilities the position calls for, as superintendents or gardeners, should apply to the National Association of Gardeners, M. C. Ebel, Secretary, 286 Fifth Avenue, New York.

The association numbers among its sustaining members, the owners of some of the foremost country estates in America.

The association makes no charge for any service it may render to employer or member.

LOCAL SOCIETIES

DAHLIA SOCIETY OF NEW JERSEY

The Dahlia Society of New Jersey will hold its first Annual Dahlia Show at the Robert Treat Hotel, Newark, New Jersey, on Thursday, Friday and Saturday, September 13, 14 and 15.

The organization, though but six months old, has grown rapidly and its members are full of enthusiasm, working hard for its success. They have taken not only the large ballroom but three large rooms adjoining. There will be every encouragement both for the amateur and commercial grower with medals and prizes donated by many outside organizations. Applications for entry may be made to Mr. Charles Walker, 264 East 32nd Street, Paterson, New Jersey.

WESTCHESTER AND FAIRFIELD HORT. SOCIETY

The regular monthly meeting of the above society was held in Greenwich, July 10, and was well attended, between fifty and sixty members being present. One member elected and three nominated for membership.

It was decided to hold the Fall Flower Show September 12-13-14, at the Y. M. C. A., Greenwich. Last year the show was a success and the profits of \$2,000 were divided between the Port Chester and Greenwich Hospitals. Again this year the show is to be held for the benefit of the two hospitals, and it is hoped a larger amount can be raised for them. The garden clubs of Greenwich, Rye, and Riverside are again uniting with us for the show which is to be on more elaborate lines than any previously held in this vicinity.

William H. Waite, of Rumson, N. J., noted for his Dahlia culture, gave us a lecture on "The Dahlia." His talk was thoroughly enjoyed by all and was one of the most instructive we have heard for some time. A rising vote of thanks was tendered Mr. Waite for his splendid lecture.

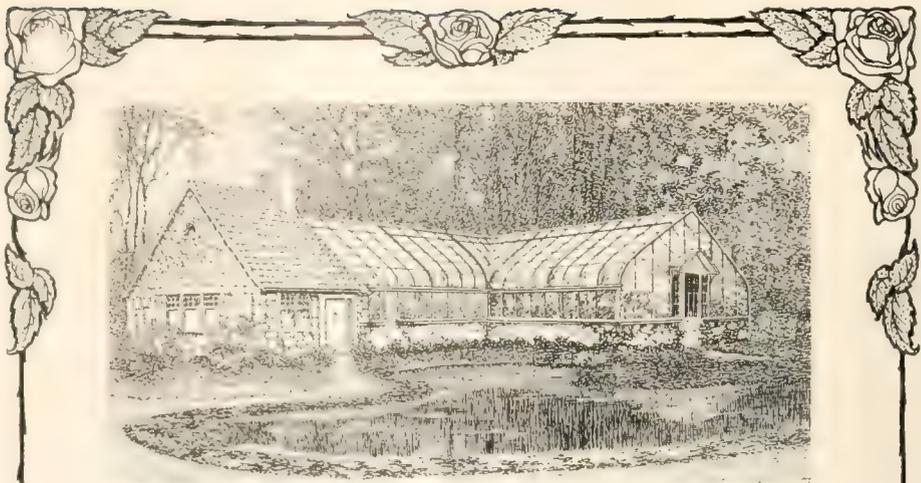

Very keen competition is being had for the A. N. Pierson and J. H. Troy fund and the society's medals, very good exhibits being shown at the meetings. George Baldwin received first for a Cattleya Hardyanna which was a splendid exhibit of this type. Edwin Beckett also exhibited a Cattleya Hardyanna receiving second. T. F. Chrystal received third for a collection of Sweet Peas. Other exhibits included a very choice vase of Hollyhocks, "Newport Pink," George Hewitt; Caladium and Kœlreuteria paniculata, W. D. Robertson; vase of Japanese Iris, Nicholas Vasiloff. For a collection of vegetables John Andrews received first and H. F. Bulpitt second.

ANDREW KNEUKER, Cor. Sec'y.

NASSAU CO. HORT. SOCIETY

The regular monthly meeting of this society was held on July 11. Vice-president Thomas Scott occupied the chair. Steven Misakawisy was elected to active membership. Messrs. Trepass, Milstead, and Nevins judged the exhibits, giving J. W. Everitt first with 12 mixed gladioli; 3 heads of cabbage; 25 string beans. There was one petition for active membership. The dahlia show will be held on Sept. 27 and 28. August exhibits will be of 6 ears of corn; vase of mixed perennials; 25 lima beans. The annual picnic will be held on August 9. Mr. Harder addressed the meeting on rat extermination, and Mr. Martin spoke on tree surgery.

ARTHUR COOK, Cor. Sec'y.

This house with its attractive curved eaves and enduring steel frame was designed especially to fit a location, within a stone's throw from the residence.

Greenhouse Convincement
What, Therefore, Is It?

Always, in whatever you buy there are two influencing factors. One is what the makers claim for the thing they make, the other—what the buyers of that thing say. With most careful buyers, claims about what *can be done* carry far less conviction, than evidence of what has *been done*.

If you are one of the latter, we have as convincing, greenhouses on the finest estates from Maine to California. Green-

houses, that were not merely built by us, but painstakingly designed to fit into the landscaping. They successfully combine the attractive with the thoroughly practical.

For considerably over half a century, we have been greenhouse specialists. Always, our Designing Department is at your disposal. To our printed matter you are most welcome. On your special request *only*, will a representative call.

How Constructed

All our four constructions have complete steel frames, either with or without metal mounted glazing bars.

- 1. Curved eaves with steel frame and exposed glazing bars.
- 2. Curved eaves with steel frame and galvanized steel I-Bar glazing bars.
- 3. Curved eaves, steel frame with galvanized steel V-Bar glazing bars.
- 4. Either number two or three with straight eaves.

No. 18 Union Stock Yards, Chicago

After thirty-one years of continuous service William P. Rich has resigned as secretary of the Massachusetts Horticultural Society. Edward I. Farrington has been chosen to succeed him.

Mr. Rich, who is now seventy years old, has seen many changes in the Society during his long tenure of office. In that time the library, which is housed on the top floor of Horticultural Hall, has become the finest and most complete horticultural library in America. Indeed, it is often called the best library of the kind in the world. It contains 25,000 books and is particularly rich in rare volumes of the sixteenth and seventeenth centuries. Mr. Rich will continue with the Society as an assistant in the library.

Mr. Farrington, the new secretary, is well known as a lecturer and magazine writer on horticultural subjects. For some years he has conducted the Boston Sunday Globe's garden column. Mr. Farrington was formerly associated with Suburban Life and for the past four years has managed Horticulture.

The Massachusetts Horticultural Society has also taken another very important step in acquiring Horticulture which will be continued as its official organ. This paper was established by the late William J. Stewart in 1904. By having an organ of this kind the Society will be able to greatly widen the scope and extent of its work.

ON HEADING LETTUCE

FREDERIC HEITTE

A TRENCH was dug 18 inches deep and 18 inches wide, the soil being thrown on both sides, 3 inches of humus was spread at the bottom, topped with 3 inches of soil; a double row was planted, the plants alternating. Pea brush was then laid crosswise on the trench until the plants recuperated from the shift, then removed and again shaded when signs of heading prevailed. This resulted in 95 per cent good heads of the amount planted. The varieties tried were "Wayahead" and "Salamander" sown May 18, both answered well to the treatment. The first picking was obtained July 22, "Wayahead" taking the lead. All remaining heads are well formed and show no signs of "bolting," whereas the same planting under ordinary conditions and treatment have not headed to satisfaction and have long past. The important point is that moisture, the principal item, is under better control as a hose was just inserted in the trench and flooded when required.

Mr. Thompson, the superintendent, shares my opinion that it is worth while doing, when quality heads of fine crisp lettuce are required during the season, when it seems to be beyond control of "bolting."

THE POSSIBILITIES OF THE GLADIOLUS

AT a regular monthly meeting of the Garden Flowers Society of Indianapolis, A. E. Kunderd, gladiolus specialist, was the principal speaker. Mr. Kunderd said: "The Gladiolus is fast becoming recognized as one of the most universally adaptable and useful of all Summer flowers. Its possibilities are just beginning to be realized. It is not an ornamental plant like a canna or coleus, and yet it adds great charm either to the border or among

roses, shrubbery, etc., and is unsurpassed as a garden attraction and as a cut flower. Matthew Crawford once said 'It has few equals and no superiors. None are more beautiful and there is nothing in sight to supersede it.'

After speaking of its history, its improvement, and possibilities of still further improvement, Mr. Kunderd added that there is much to be said on culture and growing, but never forget that the three greatest essentials to successful growing of gladioli, as of most anything else, are good soil, good and frequent cultivation, and plenty of water during the growing season. Well grown gladioli are very superior to those less carefully grown. Gladioli should not be planted too deeply as their roots are less liable to feed in the soil which is above the bulb level. In shallow soils this is important. Deep plowing or spading of soils is desirable but must be done with reference to the depth of the surface soil, as deep spading of shallow soils would bring to the surface too much of the sub-soil. A covering of four inches of soil above the corms is generally considered about the best. Mellow loam or sandy soils are better adapted to somewhat deeper planting than is a clay or heavy soil. By successive plantings from early garden making time until late in June, then following with plantings in the greenhouse from about August 10 on until the following March, one may now have blooms of these magnificent flowers almost the year round.

As a variation of the theme "Plant gladioli in your shrubbery and hardy flower borders," he recommended planting other flowers with gladioli to see what a beautiful garden one can achieve. That is, feature the gladioli, using such annuals as zinnias and marigolds to carry out the color schemes and keep continuous blossom in the beds.

WHY BUGS LEAVE HOME

Gentlemen: It is with great pleasure that I recommend Wilson's O. K. Plant Spray. I have used it on Boxwood and it has thoroughly cleaned the latter of Boxmite. I have also used it with satisfactory results in the greenhouses as well as in the garden. It is indispensable to the upkeep of the garden.
Yours truly,
HENRY A. BURGESS

*The Insecticide that
kills plant Lice
of many species*

The Insecticide of Recognized Merit for Greenhouse and Garden

APHINE is a concentrated material—mixes readily in water—efficient in its action—easily applied—free of the disagreeable odors and features of most insecticides—excellent as a wash for decorative plants.

FOR THE GARDEN—As a remedy against all sap sucking insects infesting flowers, fruits and vegetables, APHINE is most effective.

FOR THE GREENHOUSE—Applied at regular intervals (once each week or ten days) APHINE will keep plants in the greenhouse and conservatory free of insect pests.

FUNGINE—For mildew, rust and other blights affecting flowers, fruits and vegetables.

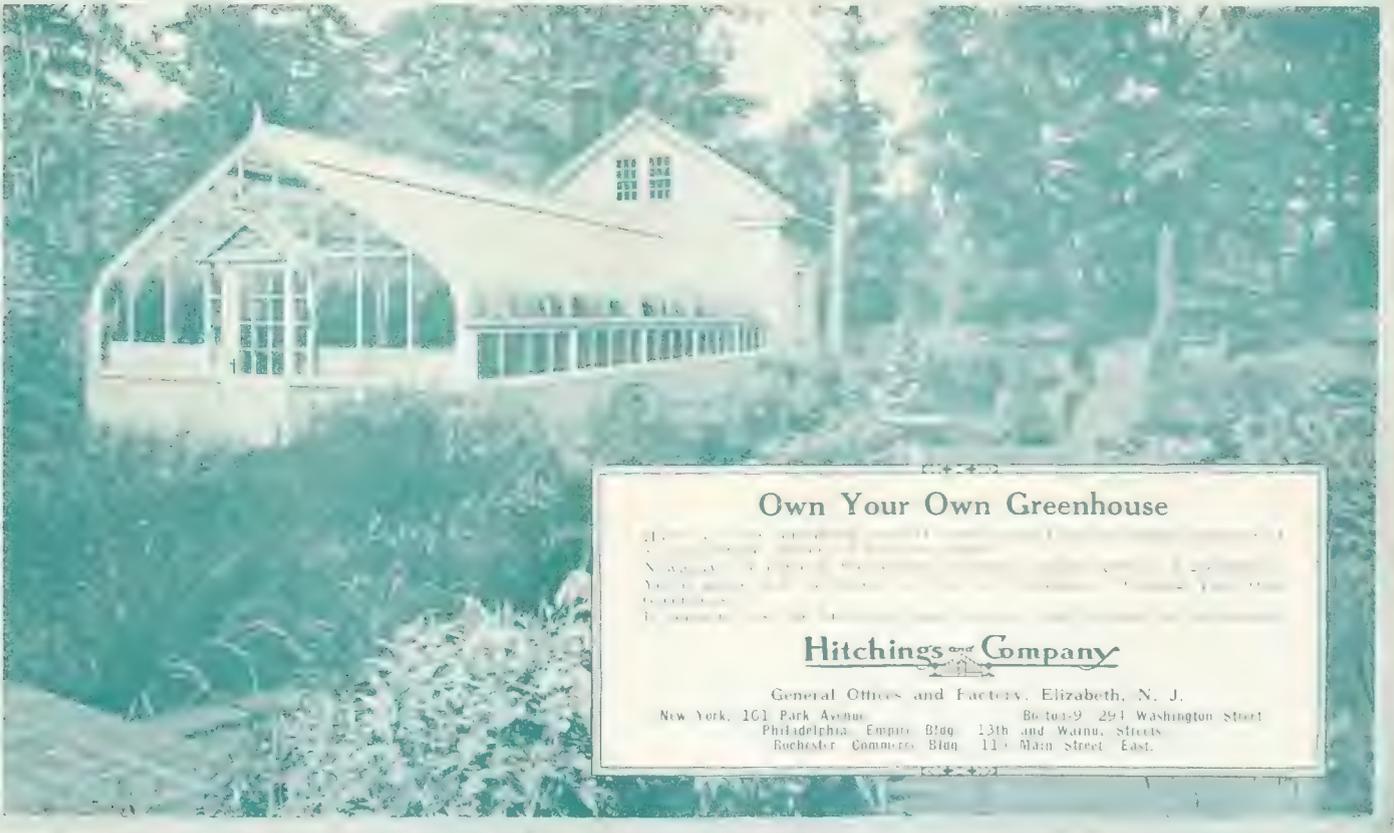

VERMINE—For worms and insects infesting the soil.

School Grounds

The tribute of John S. Kapps to Davey Tree Surgery

Troy, New York, May 2, 1923.

THE DAVEY TREE EXPERT CO., Kett, Ohio

Dear Sirs:

I noted with great interest the surgery performed by your Mr. Powell on several of the trees on the school grounds and it was a real source of pleasure to me to see how carefully and conscientiously this work was done. I look forward to a great improvement in the growth of the several trees treated last fall and I of course shall be pleased to notify you as to their progress.

With best wishes to you and Mr. Powell, I am,

Yours sincerely,

Signed JOHN S. KAPPS

Supt. of Bldg. and Grounds

Junior High School, Troy, New York

For the good of the trees and the pleasure of the community, it is highly skilled assistance. Many, like Mr. Kapps, protect their trees by Davey Tree surgery, which is a science based on a combination of study and experience. A well-trained and experienced tree surgeon is essential to the success of any tree surgery.

Tulips & Springtime

To enjoy them together in your own garden next season
Plant Schling's Bulbs This Fall

DARWINS and Cottage, single and double, early and late,—
 their lovely cups brimming with color and nodding a merry
 "good morning" to you every day for weeks—from early April to
 June in fact—How can you afford to miss them!

Order now and generously
 plant them this fall and we promise you a winter of pleasant antici-
 pation, a springtime full of delightful surprises and years of happy
 memories:—

To bring the joys of Tulip time to as many as possible we make
 the following very special offers, all bulbs guaranteed top size and
 very first quality.

Schling's Special Border Collection

Of gorgeous Darwin and Cottage Tulips

	Per 100	Per 1,000
Clara Butt—Large, single, Darwin	\$1.50	\$15.00

The Greatest Dahlia Ever Introduced

“JERSEY’S BEAUTY”

(By Wm. H. Waite)

THE TRUEST PINK Dahlia that we have ever seen. Most so-called pink Dahlias are not pink but shades of lavender. “JERSEY’S BEAUTY” does not show any trace of lavender. The nearest that we can match the true color of “JERSEY’S BEAUTY,” with Rigdway’s color chart, is “EOSINE PINK.” In comparison with other flowers, the nearest that we can come to, is the Heart of a Columbia Rose.

Apart from the beautiful color of this variety, it is absolute perfection in form, size, and stem; a true always full decorative, the pink counterpart of that glorious Dahlia, Mrs. I. de Ver Warner.

A vigorous grower, producing long strong stems, which carry the flowers straight several feet above the foliage.

Mr. Wm. H. Waite, who is the originator, has produced several outstanding meritorious varieties, from the finest of the Marean creations, but we feel that he has outclassed all his former efforts and have no hesitation in saying to all who place such confidence in us in the introduction and recommendation of new Dahlias, that it will be a very long time, before anything will be created to equal “JERSEY’S BEAUTY.”

The name practically suggested itself, for every one who saw it growing in the gardens at “Rohallion” has exclaimed, “Isn’t it a Beauty!”

Make reservations now because stock is limited which will be shipped out in the rotation in which the orders are received; tubers, delivery AFTER APRIL FIRST 1924, \$25 each, guaranteed with live eye.

NO TUBERS SOLD TO DEALERS OR GROWERS

Strong green plants, for May-June deliveries, \$10 each

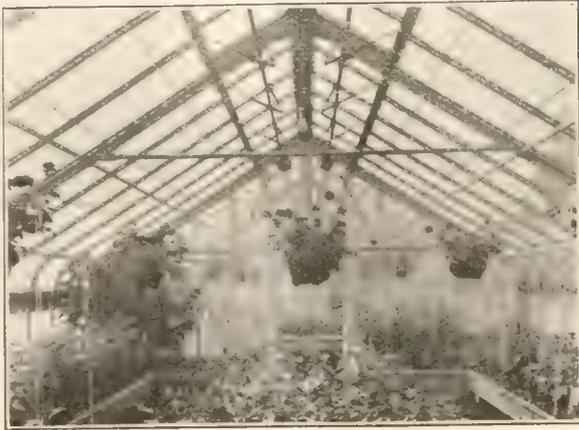

“Judge Marean has passed away, but the progeny of the very best of his creations will go on forever.”

WILSON'S O. K. PLANT SPRAY

The Answer to Why Bugs Leave Home

Ivar Ringdahl in his lecture at the New York State Agricultural College in 1922, explained *Why Bugs Leave Home*. This is what he wrote us Aug. 3, 1923.

Rome, New York, August 3, 1923

Andrew Wilson, Inc., Springfield, N. J.

Gentlemen: During the last two years I have been very conscientiously experimenting with your Wilson's O. K. Plant Spray under glass. I have used besides your product, two other very well known good insecticides, and I did not want to give the other brands up, because I have used them for years and found them fairly satisfactory.

Of late all my growers have unanimously decided that your O. K. Plant Spray is the only thing to use, and consequently I intend to use only your product from now on.

I grow 14 houses of general, assorted fancy plants and make a specialty of Cyclamen. I want to state emphatically that your Plant Spray is by far the best thing to keep Cyclamen clean.

Yours very truly,

IVAR RINGDAHL

Things and Thoughts of the Garden

WILLIAM N. CRAIG

LIBRARY
NEW YORK
HORTICULTURAL
SOCIETY

THE two predominant flowers in our gardens during August and September are Gladioli and Dahlias. As to which of these is the more popular flower there will be a difference of opinion. Taking the country as a whole, I should say that Gladioli were much in the lead, as they thrive in many sections where Dahlias are a failure. In New England there are a great and steadily growing number of enthusiasts of each, but Gladioli appear to be forging ahead faster than Dahlias. It is easily possible by making several plantings to have Gladioli in flower from mid-July until frost, and by using more of the smaller sized bulbs, the season can be greatly extended even when only one planting is made. Amateurs are in the main very eager to get large sized bulbs for planting, which, as a matter of fact, are not the best to use. For the production of spikes of exhibition quality I much prefer those of medium size. There are certain advantages which Gladioli possess over Dahlias. They may be planted from the time the ground is free from frost and workable until the middle of July, while for first class flowers for cutting, lines in the vegetable garden are to be recommended. They are a very accommodating flower and in small clumps work in very well even in the more pretentious formal gardens, provided the colors are carefully selected; they are often seen dotted in shrubberies but there they look rather unhappy and out of place. Both the *Primulinus* and *Gandavensis* types have their adherents; in the garden the latter make the holder showing, but for cutting and artistic arrangements the *Primulinus* varieties are infinitely superior, their colors also are charming, the buff, salmon-orange, apricot and other shades being especially desirable.

* * *

The advent of *G. Primulinus* gave a tremendous fillip to *Gladiolus* culture. In this connection it is interesting to remember that this species is found growing in profusion near the great Zambesi falls in Central Africa and is constantly drenched by spray in its native habitat. According to E. H. Wilson it is never dry and is a perpetual bloomer. In Florida it has developed somewhat similar traits; in that balmy state it can, of course, stay out all Winter and, in spite of long periods of drought, it is more or less a perpetual bloomer. I am referring now to the species itself, but the hybrids are proving almost equally persistent. The commercial florists object to the *Primulinus* varieties as they do not ship as well as

the older and larger type, but if properly packed they travel perfectly well. They can also be arranged so much more gracefully than the *Gandavensis* varieties. As cut flowers Gladioli are immeasurably superior to Dahlias (which are not good keepers, if cut with even a moderate length of stem). They should be cut when the first flower is open and the cut should be a slanting one. Few flowers will open all blooms on their spikes as do Gladioli, and with Asters they are easily our most valuable outdoor flowers for cutting.

* * *

We are getting each year a great number—far too many in fact—of new Gladioli. There is an evident tendency to strive after size, but all hybridizers are not obsessed with this craze. There are differences of opinion as to whether the ideal spike is one carrying all of its flowers on one side of the spike, or in a corkscrew like formation round the spike. The latter will not ship well, but they certainly arrange better in a vase or basket. The branching habit has been greatly developed in late years, and in the not distant future by the use of other species of Gladioli, I look to see the advent of a race with flowers of but moderate size on spikes which are much more branched, and with the addition of greater fragrance. The amateur who takes up Gladioli culture as a hobby is always sure of a good increase in the number of bulbs, especially where all of the little bulblets are saved. They winter very easily in any cellar which will keep potatoes. In the case of bulblets I have always found that they keep much better if some soil is mixed with them and they are carried over in paper bags.

* * *

For really effective arrangements, we cannot beat the singles and smaller sized cactus Dahlias, most of which are also profuse bloomers and hold their flowers where they can be seen. What we need today is a type which is of rather dwarf habit and throws its flowers well above the foliage, with small or medium sized flowers. Such a race would make fine garden plants. At a recent show in Manchester, Mass., a plant was exhibited in a pot of just such a type as I have in mind. It was a recent importation of Scotch origin and its dwarf habit and floriferousness are the characteristics which our present day specialists are entirely losing sight of. There will, no doubt, continue to be a place for big Dahlia flowers just as there is still a demand for large Chrysanthemums, but the

furor for the latter has passed just as that for mammoth Dahlias will peter out.

* * *

The fact that Dahlias are being more and more attacked by borers is this season discouraging a good many New England growers. That potential pest, the European corn borer, has taken a special liking to this plant. Gladioli, while not entirely immune from its attacks, have suffered very little by comparison. Dahlia tubers also do not winter as easily as Gladioli and take up considerably more room. They suffer badly from heavy winds and rains, and a very little frost finishes them, which often comes when they are at their best. In spite of these apparent drawbacks there is an increasing army of Dahlia enthusiasts in the East and at this season a drive through any part of New England will show that there is a big army of Dahlia lovers. It is good to see that the old show, fancy, pompon, and single varieties have many admirers. It is also comforting to note that all growers are not striving after ten-inch blooms.

* * *

Anyone riding through the country at this season will note the increasing use of roadside stands for the sales of produce from farms and gardens. It is one way whereby producers can place their goods in the hands of the ultimate consumers. While fruits and vegetables fill the bulk of these stands, an increasing quantity of cut flowers are sold in this way. The development of these roadside stands has caused a very greatly increased sale of flowers by those of moderate means and is doing not a little to increase the love of flowers amongst the masses.

* * *

In September there is a great scarcity of desirable hardy flowering shrubs. Berried subjects, on the other hand, are numerous and well varied. Probably the most widely grown amongst flowering shrubs and the one most heavily overplanted is *Hydrangea paniculata grandiflora*. It would almost seem as if everyone with a front lawn felt the necessity of planting one or more of these easily grown, hardy and very floriferous plants to the exclusion of other equally attractive shrubs.

H. paniculata, the type, is much more pleasing and graceful than *grandiflora*, but it is for some reason little planted. *H. paniculata præcox* has particularly handsome foliage. Of the several forms of *H. arborescens*, one named *urticifolia* is a late bloomer and was just opening on September 1. *Quercifolia* has large and very striking oak-like foliage. *H. radiata*, native of the Carolinas, is not unlike *H. cinerea* in habit but the large leaves are leathery and the cymes always come with sterile flowers. A strikingly pretty and, withal, graceful Japanese shrub is *Clerodendron trichotomum*, which has proved quite hardy in the Arnold Arboretum and is at its best during September. This shrub attains a height of ten feet; its flowers are white with a reddish brown calyx, carried on forking, slender, reddish peduncles. Even when killed to the ground, the *Clerodendron* will sprout up again and flower freely as in the case of *Buddleia*. The last-named shrub makes a great show in August and September. *B. variabilis magnifica* is much the best of the several hardy varieties and is equally good in the shrubbery and perennial border; plants always carry much finer racemes when cut down to the ground each Spring. Still another September flowering shrub, a member of the *Verbenaceæ* family, is *Vitex negundo incisa*, which stands all ordinary Winters in Massachusetts and thrives well in a rather dry and sunny exposure. While the individual lilac or

lavender colored flowers are quite small, produced as they are in loose terminal panicles five to eight inches long, they are effective. Even when not in flower this shrub is attractive on account of its foliage.

* * *

In a previous note I referred to the flowering of *Lilium giganteum* in Boston. A friend in Newport, R. I., advises me that a very fine spike, carrying a dozen flowers, was a striking feature in the attractive garden of Mrs. T. J. Emery, where Andrew J. Dorward is superintendent. I have also been told that a fine spike was produced last year in a garden in Manchester, Mass. A correspondent writes of how splendidly it used to flower with him in North Wales. At the gardens of the Royal Horticultural Society of England at Wisley there are some splendid colonies of this most noble of all lilies, which carry numerous stalks of flowers each season.

* * *

A charming pink flowering plant now in full beauty is *Chironia floribunda*, a member of the natural order *Gentianæ*. I saw a group of splendidly flowered plants in seven-inch pots at a recent show in Manchester, Mass., which appeared to interest the many society ladies present. This is by no means a new plant, having been introduced from South Africa as long ago as 1843. The *Chironias*, of which there are several species, are small, soft-wooded perennial herbs or shrubs and all are native of South Africa. They can be readily propagated from cuttings in gentle heat in Spring. They need perfect drainage and thrive well in a mixture of fibrous peat and loam with plenty of sand added. The plants referred to were rooted in the Spring of the preceding year. The small flowers produced on solitary peduncles are very numerous carried on well-rounded, shapely plants, which do not rise over a foot above the tops of the pots. This is one of the most charming Summer flowering pot plants we have. It needs cool greenhouse treatment.

* * *

Not all of us can grow Orchids, more especially tropical varieties. Some amateurs, however, are able to handle our native varieties quite successfully. Even though we cannot grow them we have the privilege of admiring them at our exhibitions, and in this connection it is interesting to know that the American Orchid Society has issued preliminary schedules for a great special show of these plants to be held in Horticultural Hall, Boston, May 8-11, 1924.

There are sixty-seven classes for plants, of which no less than twenty-three are for groups, and a supplementary schedule to be issued early in January will contain a number of cut flower classes. Five classes are allotted to native Orchids, and specialists in these latter plants have been offered greenhouse facilities for the gentle forcing of their plants. Gold, silver, and other medals, as well as silver cups are offered in dozens, mainly by the American Orchid Society, but also by the Massachusetts Horticultural Society, the Society of American Florists, the National Association of Gardeners, and a number of amateur enthusiasts. The exhibition will be the most notable of its kind ever held in America. It is planned to have all admissions free. There will be illustrated and practical lectures each day. A number of growers have for some time been making preparations for this great show, which will set a new milestone in American orchid exhibitions. All of the exhibition halls of the Massachusetts Horticultural Society will be needed to accommodate the displays and already several European specialists have announced their intention of being present.

In the Garden and in the Greenhouse

GEORGE F. STEWART

IN THE GARDEN

THE month covered by these notes (late September and early October) is as a rule here in the East the most bracing and delightful period of the whole year. The days are bright and warm, followed by cool evenings and nights, which are most enjoyable after the heat of the previous months. Unfortunately, in the locality in which I write these notes, we nearly always have a frost in September that kills and mars the beauty of many of our garden plants. Quite often we afterwards have a long spell of fine mild weather in which no frost occurs. If we had any means of staving the frost off it would help us greatly in our Fall display. Our native hardy herbaceous plants are very seldom affected by these early frosts, but it is generally the more tender annuals that we use for filling in the gaps in the borders, made by the early flowering perennials, that are cut down and blackened. However, in our profession we are contending many times with the elements of Nature, which are beyond our control, except in very limited areas.

It is a great pity that many of the so-called hardy chrysanthemums are not to be relied on without some means of protection in this section. While attending the gardeners' convention two years ago in New York, I paid a visit to my friend, James Stuart at Mamaroneck. He had a display in the middle of October of chrysanthemums in Mrs. Constable's garden that was worth going a long way to see. There was a fine range of color among them which blended well together. Our brethren in the vicinity of New York are fortunate in having these plants for such a long Fall display.

This month the harvesting of some of the crops will be in order, and preparations should now be completed to accommodate them. As soon as the potato vines die down, if the weather is at all favorable, they may be lifted. A sharp lookout needs to be made to eliminate any tubers that show the least sign of disease. They are better if dry when removed indoors, and if time permits they should be gone over a second time to take out any which have a tendency to decay. Carrots and beets may also be stored in the root cellar in clean sand.

Be sure that the onions are thoroughly dried before placing them in their winter quarters. It is necessary to spread them out thinly on a dry floor and turn them over several times to make sure that they are well ripened. The larger the onion, the poorer they keep, so we have learned from experience. It is, therefore, better to reserve the smaller ones for later use.

This month cauliflower will be heading up and the leaves are better if tied over the heads when they form. They keep cleaner and whiter for a longer period.

During this month the celery plants probably grow more rapidly than at any time since they were planted. The important operation of "earthing up" will have to be attended to at intervals of about ten days, a little at a time and often is more advisable than at long intervals. Tie up the leaves of the plants and make sure that the soil does not come in contact with the young and tender centres. Be sure that it gets abundance of water at the roots before "earthing up." Continue to use rust preventatives at this season as this is the worst time of the year for rust.

Those who grow Globe artichokes should give them some attention at this season. Flower stems need to be cut down to the ground and the exhausted soil removed

from the roots and covered by about six inches of good farmyard manure. Then cover the same with sifted coal ashes. Some protection to the roots will be necessary later.

Give the late spinach every attention as regards hoeing and thinning out the plants. Brussel sprouts should have the leaves removed to allow light and air to circulate through them which helps to make them firm.

Lettuce should be sown in frames for succession. We find it best to drop a few lettuce seed where the plant is to grow and later thin out to a single plant.

If one has plenty of space available and can maintain a temperature around 50 deg. a sowing of beans may be made indoors. I have seen excellent crops grown in eight-inch pots on a shelf in a warm greenhouse.

Collect horse manure for mushroom growing and turn it once a day to make sure that it does not get too dry. A little, good loam may be added to the mass to help it to retain moisture. When the bed is made up, allow the temperature to fall to 80 deg. before the spawn is put in.

All apples and pears that are ready for harvesting should be picked before they attain their full ripeness.

Continue to keep the flower borders and beds clear of weeds. Spread out any plants in the borders that are in flower to cover any gap that may have been made by early frost, or by plants that have passed out of flower. Make preparations for any changes in the herbaceous borders after the last of the flowers are cut down by frost. This should be done as early in the Fall as possible, so that any bulbs that are to be planted may be put in place as soon as they arrive.

Oriental poppies may be moved in September, and any of the early Spring flowering herbaceous plants.

Dicentra spectabilis, now that it can no longer be imported, can be easily divided and increased at this season. Small pieces of root will grow into nice plants if well taken care of. It was once largely used during the Winter for forcing. *Dicentra spectabilis* is one of the most beautiful of our early Summer flowering plants and lasts a long time in flower. There is a pure white form of it now very rarely seen.

Japanese Anemones will be in all their glory, unless injured by early frosts. It is a pity that in our section this quite often happens, as they are undoubtedly among the choicest of our Fall flowers. They do very well grown in tubs, and thus grown are more easily protected. There are quite a few hybrid forms of these plants, some of them very beautiful.

Another beautiful Fall flowering plant is *Cimicifuga racemosa*; the variety *simplex* is also quite common. They are among the best of our Fall flowering plants, and are perfectly hardy, doing well in shady positions. A fungus blight disease, quite often attacks them, which is very unfortunate. This Fall, however, we have seen none affected. The same also was true of Hollyhocks. Never have we seen finer foliage on these plants.

Continue to take good care of the hybrid tea roses, which remain flowering until quite late in the year if well watered, sprayed for blight, and fed.

Transplant all mid-Summer sown herbaceous plants into good soil and give them every encouragement, if intended for the borders next Summer.

Dahlias, where early frosts have not injured them, will be in all their glory. They like plenty of water during their flowering period. The rage lately seems to be after large flowers, which, to my mind, are too coarse for ef-

fective decorative work. Good straight colored singles are much better. The double flowered kinds are not nearly as free flowering as they were nearly forty years ago, when, as a boy, I first became acquainted with them. When it comes to names, well, to say the least, they are bewildering.

If the weather becomes dry, see that any lawns which have been seeded down recently are well watered; the young grass will not yet be well rooted and will suffer if neglected.

If there are any evergreens to be planted, let it be done without delay so that they may become established before Winter.

IN THE GREENHOUSE

This month is one of the hardest for the greenhouse man. Everything has to be brought into its Winter quarters, and on nearly every place plants have to be somewhat over-crowded until the chrysanthemums are out of the way. Cold frames are very useful at this season, as many of the more dwarf growing plants may be kept in them until well into December with a little protection. Care, however, must be exercised that they are well aired on all bright warm days to prevent damage from dampness.

Azaleas should be sorted out into batches, the earlier flowering varieties may be immediately placed in a cool, light, airy greenhouse. Later on a few that may be desired early in the year can be forced in a little more heat. A good cool pit is the best place for storing the main batch, watering them carefully. Any young growths that may appear around the flower buds must be picked off. Occasional waterings with soft coal soot water will keep the foliage in good color and will not stimulate young growths. A collection of the lovely Kurume azaleas ought to be secured. The different shades of color are most charming and are sure to be appreciated by anyone with refined taste.

Acacias, Heaths and all greenhouse hardwood plants, known as New Holland plants, may be kept in any light structure from which frost is kept. They resent any attempt at forcing in a high temperature. Stevia and *Buddleia asiatica* may be also treated like hardwood plants and brought into a slightly higher temperature as required.

Chrysanthemums need plenty of attention as regards feeding, as they swell their flower buds. The old standard plant food "Clay's Fertilizer" is hard to beat, and it is also safe. The plants seem to take it up as they require it. The bush plants may be staked out as soon as they set their flower buds. Put in cuttings of the Paris daisy (*Chrysanthemum frutescens*) which will make useful plants by Spring. As cut flowers they blend well with any other Spring flowers.

Give the Bouvardias a good position in an intermediate temperature. They may be fed a little if at all pot bound.

Commence watering and feeding Nerines as soon as they push up their flowers. It is not advisable to re-pot these plants as long as there is plenty of room in the pot to hold water. They flower much better when the pot is well filled with bulbs. Every greenhouse should have a batch of them, as they bloom just as other flowers are cut down with frost outdoors. Arranged with ferns their bright colors appear pretty and cheerful. *Primula sinensis*, *obconica*, *stellata*, and the early batch of *malacoides* will soon be ready for a shift into their flowering pots. They grow well in a good rich, sandy loam. *Primula kewensis* is another primrose that is useful in the Spring, both as a plant and for cut flower purposes.

A frost-proof frame of English primroses gives quantities of flowers very early in the Spring, and continues in flower quite a long while.

Keep young *finchsia* plants which were rooted about August first, potted right along; never allow them to get pot bound. Give them a rich open soil. Pinch the centres about every six joints, always taking the strongest break for a leader. The side breaks also need judicious pinchings to form nice specimens.

We have had very poor success in forcing *Iris tingitana*, since the foreign supply was cut off by our over-zealous friends in Washington. A friend in California writes to me that the whole trouble seems to be in the ripening. He says outwardly he can grow bigger and better looking bulbs than the imported ones of bygone days, but he obtains very few flowers. He, however, is not discouraged and hopes in the near future to solve the problem.

How much we owe to the pioneers in horticulture in the years behind us! It is cheering, however, to realize that we have men today in our land who, in the face of baffling problems in our life work, are keeping at it. Many of them are far from friends of their youth and living an obscure life in out of the way regions, that some day others may enjoy the fruit of their labors. How much of our honors, and pleasures belong by right to the other fellow, we should do well to think about sometimes. But we are getting away from our subject.

Iris tingitana must be grown cool and in a light position to thrive well, even if we are unsuccessful in obtaining flowering bulbs.

To those who have a house suitable for growing sweet peas, the present is a good time to start them. Three seeds to a three-and-a-half-inch pot are plenty, and if one strong plant develops from them, will be sufficient in each pot, when planting out time arrives. Keep them as cool as possible until they are transferred to their growing and flowering quarters, after which they may be kept in a night temperature of 50 deg.

Secure bulbs of such lilies as *L. candidum*, *L. Formosum*, and *L. giganteum*, also *L. Harrisii*. The last named may be forced quite early. We have noticed lately that *L. Harrisii*, which some years ago was badly affected by disease, has been much less subject to it. It would be interesting to know the reason why. I have long held the opinion that, if all the lilies mentioned above were grown from seed, they would be much more vigorous. With the exception of *L. candidum*, the others are all forms of *L. longiflorum*, and probably would not come true to form. *Giganteums* are better if placed under a bench when potted, until they are drawn up about four to five inches, as they are likely to flower too short in the stem. They like also to be kept in a steady temperature around 60 deg. until they open their first flower, when they may be kept in cool quarters for a long period. On the whole, for a private greenhouse, we like *Formosum* the best. It comes along in a lower temperature with us, much better than either *L. Harrisii* or *giganteum*, and generally has more flowers to the stem.

In the tropical house it will be better, with a few exceptions, not to excite the plants by stimulation, to make any further growth this season. Air freely on all favorable days and avoid extremely high temperature at night. The aim should be for a firm growth, so that, if they are used for any decorative work they will not suffer much.

Crotons, *Dracenas*, and any other plants which require light and sunshine to bring out their beautiful markings, may now be given a position where no shading is used. If they have been grown all Summer as they should, that is, just enough shade to keep the foliage from burning, it will do them no harm.

Roses will need all the care from now on that we are capable of giving them. Through the Fall, and until the days begin to lengthen, heavy mulching of cow

(Continued on page 224)

Crassulaceae, Their Propagation and Care for the Window Garden

DR. E. BADE

ALTHOUGH the thick leaved Crassulaceæ are the children of the sun, Nature nevertheless exposes them to the extreme conditions prevalent in deserts, steppes, mountain regions, and the alpine heights. For this reason the greater part of the plants have been forced to assume curious shapes. The most common formation found is that of the rosette where all the leaves are succulent and secrete slime, and a gelatinous rubberlike mass which protects the plants from herbivorous animals, and since much salt is also found in them the evaporation of the water, which was taken in during the rainy season, is prevented.

Notching the veins of Bryophyllum calycinum for propagation

A lessening of the leaf surface, which also tends to prevent rapid evaporation, is attained by these thick leaves.

To arrive at the conclusion that thick leaved plants should be kept as dry as possible is completely false. They should be regularly watered during their period of growth. In Winter, their season of rest, they are only watered when it becomes absolutely necessary, and then they are given only enough to keep the leaves from with-

ering. During these months they do not require much light and heat, and may, for convenience, be placed near a cellar window where the frost can not reach them.

In Spring, when the period of growth begins they must be gradually accustomed to the sunlight. They should never be taken from their Winter quarters and

placed into the direct rays of the sun, for then the leaves would only be burned.

These plants are exceptionally unassuming and require but little personal attention. For this reason they are especially fitted for the window garden, the peculiar form alone making them very attractive. The young plants should be transplanted every Spring while the older plants need only be repotted every third or fourth year. Since they have very few roots, relatively small flower

Covering the flower pot with a glass plate to keep the temperature and moisture as uniform as possible

pots should be used. Before placing the plant into the receptacle, the vent should receive a good foundation of broken potsherds. This will aid in removing the surplus water. The plants are satisfied with any sandy soil, although they do not bloom in it. If they are to produce flowers, they should be placed into a rich limy soil mixed with a little clay and sand.

After a few weeks the young plants can be transplanted

Since the majority of Crassulaceæ multiply themselves more easily with runners than they do through seeds we need not expect any other method. An interesting and unique way of propagation is shown by a member of this family, namely *Bryophyllum calycinum* which produces small plants on its leaves. After one of the leaves of this plant has been broken off near the petiole, and the place of parting has been well dried, the veins must be notched.

Notes From an Old Country Garden

ARTHUR T. JOHNSON, F. R. H. S.

ALTHOUGH the term "wild garden" is a somewhat contradictory one it serves to indicate a phase of horticulture which is becoming increasingly popular over here. It is the "outward and visible sign" of that inward desire to get away from the old formal style of gardening which once engrossed so many of us. The pendulum has swung in the opposite direction and we are borrowing, rather than rigidly excluding, some of that delightful freedom and breadth of treatment which is so characteristic of Nature's own woodland, hill-slope or river-side.

Whether the same influences are responsible for the advance made in this direction by many American gardeners I do not know. But I do know that they have often grasped the advantages of existing natural features in the making of gardens, and preserved these in all their pristine loveliness. A suitable setting must of course always be considered essential to the satisfactory creation of a wild garden, and that being so a good many of us may be debarred from indulging our fancies in such departures. But since the term wild is such an elastic one, embracing the grouping of not only native subjects but suitable exotics, it affords a very wide and varied field of work.

At the time of writing (August) a considerable part of our own wild garden is yielding some glorious masses of color, for the heathers are in bloom and it is to these that we look for the most gorgeous display at a season when the rest of the garden is comparatively dull. The majority of these heaths are grouped on a sharp, rather dry slope of light loam which is quite free from lime, and, though they have never been given any peat, they flourish abundantly.

Those heathers in flower at this season are mostly forms of our native species. The first of these to open is usually the bell heather (*Erica cinerea*) of which *E. c. rosea* and the dwarfier varieties, *E. c. atropurpurea* and *coccinea*, are probably the most attractive, but there is a pure white one with a very dark green foliage which is singularly beautiful. Then comes *E. (Calluna) vulgaris*, the true heather, or ling, of Scotland which, when bearing its fascinating white flowers, is the "White Heather"—emblem of "Good Luck" wherever the English tongue is spoken. The variety *serlei* is, I think, the finest of these whites, making a splendid bush some 3 ft. high, but there are many others, and among the colored ones there is a peculiar fascination about the very free and robust *Calluna vulgaris flore plena*, a perfectly double variety in a soft lavender tint.

Then we have the great Cornish heath (*E. vagans*) which affords a number of superb and distinct kinds ranging from white and cream through blush and rose to crimson, and the very charming Dorset heath (*E. ciliaris*). This last is the only one of our native heathers which may be considered a trifle tender, but it is one of the most beautiful of all, the very large bells of rosy purple, or white in the variety *alba*, being produced in long spikes which stand above the semi-prostrate masses of soft emerald green, rather pubescent, foliage. Another very attractive species is the cross-leaved heath (*E. tetralix*) which includes many varieties, the large, almost globular, bells being set in whorls at the ends of the growths.

In addition to the above there are, of course, a host of others and what makes most of these *Ericas* appeal so strongly to many of us is not only their peculiar beauty

but their ability to put up with dry soils and the fact that, once established, they never need any attention but go on for many seasons, increasing in beauty year by year. Moreover, by growing in conjunction with the above a selection of Mediterranean and other southern and alpine species we are enabled to enjoy masses of heather in full bloom at all times from January to December. And some of these Winter bloomers, such as *carnea* (herbacea) and *darleyensis* (hybrida) which flower from the end of the year to Spring, are as hardy as an oak.

America is well represented in our heath garden by the *Bryanthus (Menziesia) empetrifomis* of the Rockies, which is a gem of the first water, giving us its delightful sprays of rose-pink bells in Spring and again in the later Summer. Another tiny shrub, *B. erectus*, said to be a hybrid between *Rhodothamnus* and *Kalmia*, but bearing a much closer resemblance to *B. empetrifomis* than to either, is a charming little plant with a yew-like foliage and pink, waxen blossoms which might be taken to be those of some diminutive azalea. *Menziesia Breweri*, from cool places in the heights of the California Sierras, is another of this fascinating race that the New World has given us, and then there are among other American ericaceous things of dwarf stature which make themselves at home with our heaths, the semi-prostrate *Vaccinium ovatum* of the Pacific Coast, *V. buxifolia* for carpeting the more shady spots, *Arctostaphylos uva-ursi* and *californica* and others of that clan, and the very choice and dainty *Cassiope (Andromeda) tetragona* which flourishes so abundantly throughout the more northerly ranges of the Rocky Mountains.

The North American Sweet Pepper Bush (*Clethra alnifolia*) also claims attention, since it is now opening its fragrant sprays of white flowers, and near this we have another species, *C. acuminata*, native I believe of the Alleghanies, with rather narrower leaves and creamy, sweet-scented corymbs of bloom. *C. tomentosa* is a good and distinct form of the former with white, woolly undersides to its leaves. These *clethras* also belong to the ericaceous group and they are happiest in cool, peaty land such as that in which *Rhododendrons* thrive. Suitable companions for the pepper bushes are the pretty *Pieris floribunda* and *Zenobia speciosa*, a very beautiful species from the Southern States of America, and quite hardy here, bearing elegant sprays of white, globular flowers like lily-of-the-valley.

In the cooler, more shady, parts of our wild garden the willow gentians (*G. asclepiadea*) make a most striking effect. These consist of a variety of forms, the usual type sending up gracefully arched stems set with twin pairs of leaves at the axils of which are produced the large, bell-shaped flowers varying in shade from an ultramarine blue to a clear, luminous azure. In some instances the willow gentian will attain a height of nearly 4 feet and there is a very charming pure white variety which always looks its best in the half shade of woods associated with hardy ferns and other suitable subjects of the kind.

Though it needs full exposure *G. septemfida*, the crested-gentian of the Caucasus, also does admirably in our loamy soil intermixed with a little leaf-mould. This is, indeed, one of the easiest of its fascinating race and it is particularly valuable inasmuch as it creates fine drifts of rich blue during August and September when so

(Continued on page 224)

Lifting and Wintering Tender Bulbs and Tubers

FLORUM AMATOR

SUMMER has passed and Autumn is here. Before many weeks have gone frost will begin to crust the surface soil in our gardens in the night, and force us to dig and store our tender flowering bulbs, tubers and roots, if we desire to save them for replanting next Spring. This is a work which permits no postponement, for if frost once penetrates the soil deeply enough to freeze hard our Summer flowering bulbs and tubers, our stock of these will be lost.

The three kinds of bulbs, tubers and roots most planted by flower lovers are the *Gladiolus*, *Dahlia* and *Canna*. The first and hardiest of these is not a true bulb, but corm; the second and more tender is a tuber; and the third equally, at least, and perhaps more tender than the second, is a rhizome or root-stock. Let us consider the Autumn digging and Winter storage of these in reverse order.

As soon as the first light frosts of Autumn have nipped the leaves of our *Cannas*, we should allow the tops to dry for a few days, unless there is immediate danger of a freeze, which will penetrate to the full depth of the *Canna* roots, and then dig the roots up with a spading fork and let them dry with some earth on them for a day in the open air. They should not be exposed outdoors for even a single night, after they are dug, to the danger of even a light frost. *Cannas* should never be left in the ground until heavy frosts penetrate the soil deep enough to freeze the roots, for frost-bitten *Canna* roots will not winter over satisfactorily no matter how well they are cared for. After a day's drying in the open air, remove the tops close down to the roots with a sharp knife, and then place the roots on shelves in a cellar in which Irish potatoes will keep well. This is a rule given by the "authorities" generally, as regards the place for wintering *Canna* roots, but we are inclined to think that *Canna* roots winter best in a room or cellar where the temperature is considerably higher, and the atmosphere drier than is best for keeping Irish potatoes. Perhaps we may safely keep the heavier roots in either degree of temperature and humidity but the weaker roots in the lower and greater humidity where they will not dry up. It is very important that *Canna* roots in storage should not get too warm or too moist before cold weather sets in. In case the roots, when dug and dried do not retain much earth, a covering of light soil placed over them will help to keep them. If our *Canna* plants are fully matured at digging time, and the roots well cured, generally they are wintered over without much loss, but roots of small immature feeble plants are difficult to keep. The earlier *Canna* roots are started into growth in Spring the less the loss of roots. Commercial growers of bedding plants put their *Canna* roots into pots or flats and start them into growth under glass in mid-February or early March.

Dahlia tubers should not be left in the ground until heavy frosts penetrate the soil deep enough to frost the tubers. Frosted *Dahlia* tubers will not winter over even under the best conditions. As soon as frost has killed the foliage, cut off with a fine-toothed hand-saw squarely, root obliquely, the stalks at the surface of the ground. The advantage of a saw over a pruning knife is that in Spring when we are dividing our *Dahlia* clumps, we are not as liable to wound our

hands with the square end of the stalk as left by the saw as we are by the sharp, slanting, dry end left by the pruning knife. Dig the tubers very carefully with a spading fork so as not to break them from the stem, for tubers separated from the stem are worthless. Extra care in digging must be taken with such varieties as have tubers with long, weak necks. We should avoid digging when the ground is wet. Remove after digging as much soil as possible by rapping on the end of the stalks with a mallet or light hammer, the clump of tubers being held up a little at the same time from the ground. After this allow the tubers to dry, but only for a few hours. Next pack the clumps of tubers, the stalk end down, so that any juice or water in the stalks may run out, in barrels or boxes very thickly lined with newspapers and then cover heavily with newspapers, and immediately put the head into the barrel or cover on box and nail up tightly so that mice cannot possibly get in. Place in a cellar or room free from frost and where the temperature is not over forty-five to fifty degrees. Some careful *Dahlia* growers, after labeling each clump, which should be done in any case, wrap each separately in newspaper before placing in box or barrel. Where the air in the place where the *Dahlias* must be kept is very dry, they place a thick covering of leaves or moss over the top of the barrel or box of clumps before nailing up.

If *Gladiolus* corms were set deep as they should be at planting time, they can safely be left in the ground later than *Dahlia* tubers or *Canna* roots, but, of course, they must not be left so late that the frost penetrates the soil deep enough to freeze them. We have, however, known *Gladiolus* occasionally under favorable conditions to winter over in the garden, but have never seen a *Dahlia* or *Canna* survive the Winter in the garden.

In digging *Gladiolus* we raise the corms by pushing a spading fork under them, lift them out by their tops and lay them on the ground to dry. They may be ripened fully in the open garden if the weather is favorable. After they are dry and ripened, we cut off the tops close to the corms, and pull off from the bottom of the new corms the old corms and roots. If the weather is unfavorable for drying and cleaning in the open, the corms immediately on digging may be brought under cover and dried, and topped and cleaned there. The corms should never be left out in the garden and exposed to a frost after they are dug. All kinds of bulbs, tubers and roots will endure more frost when in the ground than when out. After the corms are cleaned, we place them in rather thin layers in crates or in peach baskets fairly full and store them in a dry place where the temperature is from forty to fifty or even a few degrees higher if necessary. Our experience has been that *Gladiolus* corms placed in a rather dry atmosphere and fairly high temperature keep in better condition and respond more quickly when planted the following season than corms kept in a rather low temperature and somewhat humid atmosphere.

Montbretias, *Watsonias*, *Zephyranthes candida* and *rosea*, *Sprekelia formosissima*, and *Bessera* should be lifted at the same time and wintered in the same way

as *Gladiolus*, except that *Montbretias* should be stored in dry sand.

The tubers of *Richardia albo-maculata* and of *Commelina cœlestis* are dug at the same time and wintered by the same method as *Dahlias*, but *Commelina* should be planted out in Spring without being allowed to start into growth.

Tigridias after the first hard frost should be lifted with their tops on, tied into bunches and hung up in a dry cellar or room in such a way that the mice, which are very fond of them, cannot get at them. If hung in a moist cellar, they will rot. The tops can be cut off and the bulbs be put in mice-proof, but well ventilated boxes.

Calochortus, when frost comes, should be dug and put in dry moss or sand and kept dry and warm during the Winter. They can also be wintered in the ground if thoroughly protected from water and frost.

Tuberous-rooted *Begonias*, if growing in outdoor beds, should be lifted on the coming of frost and dried off, and then placed in dry earth or sand, and kept in a warm, dry place. Not later than the first part of the following March they should be potted and started into growth again, as after that date they deteriorate.

Tuberoses, after frost, should be taken up and their tops cut off about two inches above the bulbs and the bulbs stored in a dry room where the temperature is not below forty degrees.

Milla biflora, not long after the first hard frost, should be lifted and dried out, and put in flats about two inches deep and stored with the *Gladiolus*. When the leaves of *Ranunculus* separate from the roots by a gentle pull and the leaves of *Anemone coronaria* die down, it is time to take them up without any delay whatever. After they are cleaned up, the bulbs should be put in a shady place and turned until entirely dry. If kept dry, the tubers of the *Ranunculus* will retain their vitality for two or three years. *Ranunculus* is really a cool greenhouse plant, but is grown successfully outdoors in frames.

NOTES FROM AN OLD COUNTRY GARDEN

(Continued from page 222)

many flowers have gone over. The individual blossoms on *G. septemfida* are deeply bell-shaped, often more than one inch across and each of the many nine inch stems put up by a hearty plant will frequently bear as many as 15 of these noble flowers. Though sometimes listed as a distinct species *G. lagodechiana* is only a slightly smaller, more prostrate, form of the above with blossoms of rather a paler blue.

Just after these comes the much newer *G. Farreri*, a superb species which has won its way into all good gardens not only on account of its unrivalled beauty but because it is, as gentians go, by no means a difficult subject. In the late Mr. Farrer's own words, this wonderful plant sends out "many flopping, slender shoots clad in very narrow foliage, and ending each in a single, huge, up-turned trumpet, wide-mouthed and of an indescribably fierce and luminous Cambridge blue within (with a clear white throat) which, without, long vandykes of periwinkle-purple alternate with swelling panels of nankeen outlined in violet and with a violet median line. . . . It is by far the most astoundingly beautiful of its race, reducing *G. verna* and *G. gentianella* to the dimmest acolytes." Need one say more in praise of what is one of the most entrancing plants that the sumptuous treasure gardens of Tibet have yet yielded?

The kniphofias, or red-hot poker plants, have always been favorites in this country, for they afford just those fiery tints which harmonize so happily with the leaf color

of Autumn, and they are among the most valuable and suitable of wild garden subjects. Fine as are the many tall species and varieties of these noble plants there are many smaller ones which, if not so well known, are rapidly coming to the front with us. This is not only because their shorter stature and less bulky growth renders them so suitable for rock-garden and border as well as for the foreground of wild garden or woodland groupings, but it is on account of the brilliance of their colors and long season of blossoming. Possessed of such excellent kinds as *K. Nelsoni*, *rufa*, *corallina*, *Macowani* and a host of others, we can now enjoy the brilliant yellows and reds, the flaming vermilion and crimson and orange tones of these stately little 2-3 foot torch lilies from June to November, for unlike many of the older kinds, the same plants will often yield successive sheaves of bloom spikes the season through.

I am tempted to mention one more family of plants which are of the utmost value in the wild garden, woodland or unconventional border and that is the genus *Verbascum*, or the mulleins, as they are familiarly known. There are so many excellent varieties of mulleins now in cultivation that one hardly dares to make comparisons. Great improvements have been made in both color and form of many varieties from the 18-inch *V. phoeniceum* in various shades of purple and buff to *V. olympicum* and *parnassum*, with their noble candelabras of large yellow flowers and handsome foliage towering to a height of eight feet or more. There are also some exceedingly lovely kinds of more moderate height in a color usually described as rosy-fawn, and then we have those coppery-apricot shades which are not less pleasing in woodland shade than the citron and primrose yellows. These eminently stately plants are, for the most part, biennials, but one is amply repaid for the trouble entailed in maintaining a stock where this is not ensured by self-sown seed.

IN THE GARDEN AND GREENHOUSE

(Continued from page 220)

manure we avoid. Experience has proved to our satisfaction that we get just as quick and a much firmer growth by weekly sprinklings of Clay's Fertilizer, bone meal, dried blood, and hen manure, during the short days. We use one of the above, each week in rotation, if possible. Hen manure we are very careful with, because it throws off ammonia quite freely and would soon damage the foliage, unless the air circulates freely. A little air on a rose house all night anyway is far better for the plants, if one has sufficient heating radiation.

In orchid growing, the aim should be to grow the plants with as little shade as possible. We have noticed that where this is done the plants flower more freely and the flowers have more substance to them. Movable shading is by far the best, and after seeing and having had experience with many different types, I have found that these plants, with the exception of the cool orchids, which require a heavier shade to keep them cool during the extreme heat of Summer, require shading—double cheesecloth is the best for this purpose. Early in the season a single thickness is sufficient, and also after the middle of September, if any unusual hot days come along. Plenty of fresh air is at all seasons in order, and during cold weather it is better for the health of the plants to use more fire heat and moisture, rather than deprive them of it.

See that pot fruit trees which are to be forced early get every chance to ripen their fruiting wood. Strawberry plants in pots for forcing next Winter must not suffer neglect in any way. Feed and water them regularly; the better the crown the more fruit will result, also better quality, which is the aim of the fruit grower.

ON THE DEVELOPMENT OF AMERICAN PRODUCTS

AZALEAS, Rhododendrons and Boxwood are being grown in different sections, but this is a slow operation at best and they are not yet available in anything like adequate commercial quantities. There is a question whether they can be produced on a profitable basis. However, we understand that a few growers are making progress in growing Indian Azaleas in different sections, some in the East and some on the Pacific Coast, and particularly the new Kurume type of Azalea, which promises to become an important plant when produced in sufficient quantity.

The inclination has generally been to substitute quick growing plants, such as Cyclamen, Begonias, Hydrangeas, pot Roses and a few other plants, which can be produced quickly and cheaply. When it comes to growing plants that take a long period of time to produce, our growers have not the inclination to work along these lines, nor have they the skilled labor needed to produce them. This is particularly true around the large industrial centers where the labor situation is acute.

The promulgation of Quarantine 37 was sudden and drastic and there is a wide difference in opinion in regard to the necessity and advisability of this action. There is a tendency to still further restrict the importation of the few plants that are now permitted. We understand that the Federal Horticultural Board is now getting expressions of opinion in regard to the advisability of an embargo on Manetti stocks. This is one of the most important of the few remaining articles that are now permitted and one of the most important articles imported by florists; an embargo on it would be a serious blow to the greenhouse Rose growing industry of the country. There are no supplies of Manetti available in this country and an embargo on this material would affect every Rose grower in the country, as grafted Roses are now considered absolutely essential. We have accommodated ourselves to the present restrictions as far as possible, but any further embargo on the few articles now permitted would be a catastrophe, until it had proved and developed that we could furnish adequate home-grown supplies.

So far as the successful home production of Lily bulbs from a commercial standpoint is concerned, there is reason to question whether they can be grown here. Forty years ago claims were made that Lily bulbs would be grown in this country and plantings were made in California, Georgia, Florida and various other places in the South, and at that time there was every incentive on account of the scarcity and high prices of bulbs, but although 40 years have elapsed, no substantial progress has been made in their cultivation.

In regard to Narcissi, while undoubtedly there may be more opportunity for growing these successfully, still attempts have been made to grow them for several years. One particular case is recalled where a number of experienced Guernsey growers located in Virginia with the idea of growing varieties of Narcissus in this country; but after several years the experiment proved a failure.

Claims have been made that Tulips are being grown successfully here, but in nothing like adequate quantities; and the blooming qualities of the bulbs still remain to be proven. While some varieties of bulbs may be grown here, it must be remembered that there is only a certain area in Holland where Tulips can be grown to produce good blooming bulbs for forcing purposes. The Hollanders found this out to their sorrow when they tried to grow Tulips in other sections of Holland, and it still remains to be proven whether the easier grown Narcissi, like the Paperwhites, can be grown and will produce satisfactory flowering bulbs for forcing. Particular climatic

conditions and soil are necessary to produce good flowering stock.

Of course, in the production of new varieties of plants, there is a great field and opportunity for our hybridizers. This is particularly true in the case of Roses. At the present time, most of the principal commercial varieties for Winter-flowering are varieties which originated in this country, and many of the most important are products of E. G. Hill. This shows what skill and enthusiasm will accomplish. Mr. Hill calls attention to several new Roses which he saw on the Pacific Coast recently. The one outstanding variety, which he saw at Portland, was Bonnie Prince; this with another new Rose called Imperial Potentate, offer two charming additions to our collection.—*Extracts from a report submitted by F. R. Pierson before convention of Society of American Florists.*

DAHLIAS FROM SEED

NOT every one is aware of the fact that dahlias may be raised in one season from seeds as readily as from tubers, and moreover the seeds have the advantage of being less expensive. Definite named varieties cannot be expected from seeds as the plants are variable, but when flowers of various forms and sizes are permitted in the garden the results are very satisfactory. It might be well to mention, however, that the best plants can be expected from selected seeds of double varieties which most seed

Dahlias from seed started March 27, picked September 20, 1922

firms feature. Of course, some single varieties will appear, but frequently they are pretty enough to be worth saving. Dahlias raised from seed usually produce good tubers the first season, and when a particularly fine variety is secured it can be perpetuated by dividing the tubers in subsequent years. Some gardeners raising dahlias from seed and securing a great variety of good flowers are tempted to name them and place the tubers on sale. The varieties of dahlias, as well as of many other flowers, are already so very great and many of them so similar that any attempt to introduce new kinds without first registering them with the particular flower society should be discouraged.

To obtain best results the dahlias should be started in—

On Forest Conservation and Its Relation to Plant Production

GEORGE H. WIRT

MR. CHAIRMAN, Ladies and Gentlemen: I note by the program that you have very graciously given me the honor of representing the great Governor of a great Commonwealth. I need not tell you that Mr. Pinchot is interested in your organization, because I see by the list of sustaining members that his name is in the Pennsylvania list. Anyone who has been in touch with work of your kind and any other kind of work that has to do with the conservation of natural resources knows where Mr. Pinchot stands on the proposition. He is with you not only in Pennsylvania but in the Nation, and I feel it a great honor to be able to come here to Pittsburgh to be with you people, not merely because it has been placed upon the program that I represent Mr. Pinchot, but from a personal standpoint, to be able to talk to you a few minutes about my own chosen work.

So I tell you, as representing the Commonwealth of Pennsylvania, that we welcome you who come from other states into a Commonwealth where we have been proud to say we have the garden spot of the world. But also, as one of the previous speakers has said, we have in Pennsylvania places that are equal to the Sahara Desert for barrenness. It may or may not be of interest to you to know that Pennsylvania has probably close to three million acres of waste land that at one time was cleared for farms and gardens and today is abandoned.

I find in the educational work over the State—and it is a mighty difficult proposition—that in order to create any enthusiasm in forest protection we have got to find some point of contact between the forest and the people with whom you are talking and dealing. Now where do you touch the forest and where does the forest touch you and your interests?

Well, from my knowledge—I will say limited knowledge of plant life, I know that one of the most essential factors in the success of plant production is moisture, that moisture must be available either in the soil or in the atmosphere and usually it must be in both in sufficient quantities, else you are stumped, that is all there is to it, and your efforts have been in vain.

The water table, we are told, in Pennsylvania has dropped on an average of twenty-seven feet from what it was fifty years ago. Do you realize, men, what that means to the agricultural interests of this Commonwealth? Stop to think about it. Has that anything to do with explaining why we have three million acres of waste farm land in Pennsylvania?

Tie up with that fact the fact that the deforesting of this state has been accomplished practically within the last fifty years, and there isn't any question to the fact that the forests on the hillsides of Pennsylvania and the forests on the hillsides of your state, wherever you are from, are nothing more nor less than God's reservoir for the maintenance and constant supply of the general water table of the Commonwealth.

Now the matter of moisture in the atmosphere. You people know that all plants transpire moisture. They give moisture off through their leaves and foliage and stems and so on. The whole plant body to a large extent is giving off moisture. The forest gives off tremendous quantities of moisture, but when there is no forest that moisture is not taken from the soil and given back into the atmosphere to come down over your gardens and over your farms supplying your crops with moisture, but instead of that the winds that come across our denuded mountains and hilltops come with moisture taken out of them and when they strike your gardens and strike your

The members of the National Association of Gardeners assembled on the lawn of the estate of

crops, instead of giving moisture they in turn take the moisture somewhere else.

So I feel that the protection of forests and the replacing of forests on the denuded lands of this state or of any other state is of intense interest to you because of the water moisture supply which those forests will guarantee not only to the immediate work in which you are interested, but very largely to the insurance of a constant moisture supply for those who come after you.

I need not mention to you from the economic standpoint of timber supply the value of forests. It affects you not only as gardeners but as individual citizens of these United States, and if you haven't considered this proposition as to where and how you are tied up to the forests because of your demand for wood, I only ask you to read any of the bulletins which you can get upon request bearing upon the subject, and many of them are brief. Get in touch with your own state forester and see what the situation is in your own state.

Just let me give you briefly the situation in Pennsylvania. There is not enough timber cut and harvested in the State of Pennsylvania, all over this state, made up of twenty-eight million acres or more, to supply the lumber needs of Pittsburgh and its immediate surroundings, and some time ago in connection with a meeting which we had in Harrisburg of timber users and others, the proposition was worked out so that ex-Governor Sproul might make an effective appeal to the timber users to get their support for the protection of forests, and this is the amazing fact that we found and ex-Governor Sproul was able to make this expression:

"There is not enough timber raised in the State of Pennsylvania—I mean cut and harvested in the State of Pennsylvania, to furnish rough boxes for the people that die in this state annually."

Now that very same condition of affairs exists in some of the states and practically all of the states from which you come, and it is not simply a situation in these eastern states and in the central western states and in the southern states, it is getting to be a condition even in the west-

ern states where practically the majority of our timber supply now is.

Now just briefly from the standpoint of forest protection. First, there are a great many people who can't see the economic value in beautiful things, and that seems to be the thing that the people on the other side of the pond throw at the American people quite frequently, that we are a bunch of money grabbers and we can't see the æsthetic side of things. Thank God we are getting past that stage in America, and it is your association and associations like yours that are helping the American people to see something more than simply dollars and cents. We are looking out into the open and seeing the beautiful things of life, and we are willing to spend our life and our effort in making the scenery and the country surrounding our homes and our particular work more beautiful.

Why? For the fellow who happens to own the land? No? Outside of a little home that I own in Harrisburg I don't own a foot of land in Pennsylvania, but there isn't a man in Pennsylvania who gets more pleasure out of the beautiful things that other people have than I do and I don't envy them a bit; and that is so with you as gardeners, and you are working not simply for the man who has the land and money to pay you, but you are working for the pleasure of everybody who comes in contact with the beautiful things that you are doing.

And so from the standpoint of forest protection, I ask you if you want, to go into God's outdoors to recuperate, for recreation, to recreate your physical body and your mental body and your spiritual soul. You would not in God's country pick out a burned over forest area because it is not beautiful, and so you don't want anybody else to go into that kind of country and you don't want to see that kind of country. Neither do I. But this Spring in the State of Pennsylvania there were almost three hundred thousand acres of forest land made desolate by forest fires, three hundred thousand acres! In some of your states that area has been increased, I mean, there were more acres than that burned over. In certain areas of certain states there were less than that.

(Continued on page 240)

Lyon, Sewickley, Pa., during the time of its convention, held in Pittsburgh, August 14-17.

THE ROSE OF SHARON

THIS is the season of the year when we appreciate the merits of the Rose of Sharon (*Hibiscus syriacus*) with their Hollyhock-like blooms of many colors. There may be more choice Summer flowering shrubs, but if we were asked for the one that required the least attention, that is not exacting as to soil requirements and will even tolerate adverse city atmospheric conditions, our selection would be the Rose of Sharon. Yes, and it will grow in the shade, though it should not be expected to flower as freely in this position. From July until frost its flowers brighten the garden and landscape.

One may obtain a wide range of color in pinks, blue and pure white, and while we favor the single sorts, the double varieties are available for those who believe they last longer and they do not have the seed pods which some would consider as not ornamental. *Totus albus* is the popular single white; *cœlestis*, a beautiful single blue, and single pink does not appear to have been given any other name. Bicolor is a double cream with crimson center; *Boule de Feu* is a red; *Lady Stanley*, a double blush pink; *Compte de Flanders*, a dark red (double), and *carnea plena*, a double rose. For those who like a variegated foliage there is the old *Hibiscus syriacus variegata*, whose buds never open and the improved variety, *Meehanii*, having a single violet flower. The latter, as with other desirable sorts, is grafted on the roots of seedlings, though propagation may be done by cuttings also from seed if the color of bloom is not essential.

Many use the Rose of Sharon for hedge purposes, either alone or in conjunction with a screen of Lombardy Poplars. We prefer mixed colors for a hedge, with the lighter ones predominating. Massed in the background of shrubbery borders and as single tree form specimens it may be used. Although pruning is not necessary, stronger flowering wood is obtained by cutting back, in Winter or Spring, the new wood to one or two eyes, as with the *Hydrangea paniculata* and *grandiflora*, and thinning out superfluous branches as needed. This treatment also insures a shapely plant and keeps it in bounds.—*Florists' Exchange*.

WHAT IS A GARDENER?

WHAT is a gardener? He has been pictured in so many ways—good, bad and ridiculous—that to most people he is a conundrum. I have seen him pictured in many ways that were anything but flattering and which did not convey a sensible idea of what he was like or what he was supposed to do; but artists, I suppose, have license to apply a ludicrous idea to anyone. However, the gardener is a good natured fellow usually and does not worry over a caricature—wise or unwise.

"There are two varieties of the genus 'gardener,' one good for something and the other good for nothing. The first kind is scarce but, alas, the second variety abounds—the country is full of its kind, and one of the objects of this association should be to find some means of eradicating him root and branch, so as to allow the good variety to flourish and bloom to full capacity. The latter comes of vigorous stock, is healthy, lives in any climate, and there is no telling to what proportions he might attain, or to what heights his genius might rise. I believe there is a great deal of talent, energy and ambition in his make-up. We have with us today many of the old type of gardener—he who served an apprenticeship, who came through the 'College of Hard Knocks.' He has not much theory, does not go far out of the beaten track, has the range of plant growing in his grasp, eschews most literature and allied sciences, but is willing to 'swap experi-

ences with a fellow gardener' in a most practical and the best man in the world as a citizen generally; he'll take all that you like to give him and will give you anything you ask for, if he has it.

"The new type of a gardener is different and it is about him that I wish to speak today. He is not so much an all-round man, but specializes more; perhaps his preference is for one phase of plant growing, or even some particular plant. I am a great believer in specialties, but I like to see a man be an all-round man, if possible, as well. Hitherto the status of the gardener in Canada has been anything but flattering and the consequence has been humility, low wages and erroneous ideas as to his ability. His value to the community cannot be questioned. To the plant loving public his responsibility is great, in that good examples of his skill are always in great demand for the beautification of our home surroundings, whether those of peer or peasant, whether public or private. His field is also the introduction of new ideas and improvements in the cultivation of flowers, fruits and vegetables.

"A word to the gardener himself. It depends to a very great extent, on you yourselves, whether you rise above your present status. As before mentioned, in the past you have been kept down and have accepted the most modest consideration. Your value depends on how much you know and whether you are willing and ambitious to learn more and progress; to put your ideas into practical shape. Educated gardeners are today in great demand; in fact, the market has never been glutted with good men. If you seek anything earnestly the chances are invariably in your favor. It is not necessary to proclaim your prowess as a skilled man from the hilltops and brag about it. A man is usually judged on his merits or results and treated accordingly (at least this is my own observation) and as a consequence it is the position that seeks the man, not the man the position.—*Extracts from an address by W. J. Potter, Toronto, before Canadian Gardeners' & Florists' Association.*

DAHLIAS FROM SEED

(Continued from page 225.)

doors in some sunny window about the first part of April. The seed should be planted in boxes containing finely sifted soil and covered about a quarter of an inch. The soil must always be kept moist, and it is better if the box is covered with a pane of glass or piece of paper until the seeds break through the surface. The boxes should be kept in a cool room, as rapid growth in a warm room is detrimental to the plants. When the seedlings are about two inches high they should be transplanted into other boxes, being spaced two inches apart, or, better still, they should be potted in small pots. Care must be exercised not to let the plants become pot-bound at any time, and they should be shifted into larger pots when the roots become too crowded at the base of the ball of soil in the pot. If a hot-bed or cold-frame is available good stocky plants can be had for planting outdoors some time in May. After planting out, two systems of training may be practiced: (1) All side shoots may be pinched off, only the central shoot being allowed to grow. This method will produce few but very fine flowers. (2) When quantity of bloom is the object in the garden the plants may be pinched to about four main branches. No matter how they are trained, however, dahlias should always be staked, as sometimes a Summer storm lays them flat.

Failure with dahlias one year should not discourage the amateur from trying a second time. The behavior of the plants varies from year to year and unless conditions are ideal they will grow but give very few blooms. Except in a few favored localities in this country dahlia seasons are

Foreign Exchange Department

USE OF FLOWERING SHRUBS—It is with great interest that I read the article on Flowering Shrubs. It is not only a regrettable, but an astonishing fact that little use is made of this very interesting and beautiful branch of horticulture. This must surely be due to ignorance of the subject. This ignorance does not extend to public parks only, but it is also noticeable in nearly all good private town gardens.

Living in a big residential district, it is particularly tragic to my notice that it is possible to walk up drive after drive where the imagination of the householder seems never to have got beyond Aucubas, Laurestinus, Laurels, the more common Rhododendrons, variegated Privets, and an odd Maple, the last appearing to have come there by mistake. All these have their place, but they seem rather overdone. This choice collection is usually massed together far too closely, so that no shrub is allowed to attain its proper form, and is usually pruned in a manner to prevent all possibility of flowering. It seems, also, a rather common failing to allow shrubs to run out. They are left to take care of themselves for a number of years, when the owner suddenly becomes aware that his shrubs are leggy and very ugly. They are then ruthlessly cut nearly to the ground, and have to start their struggle anew. It never seems to occur to the owners that this state of things could, and should, be prevented by a little judicious annual pruning.

There are so many common and quite hardy flowering shrubs which need only the most ordinary cultivation and are quite independent as to soil. Think of the many beautiful Viburnums, the different-colored Weigelas, Cydonias, and Cytisus, the Buddleias, including *B. Veitchiana*, with its long purple racemes, and *B. globosa*, with its bright yellow balls, *Kerria japonica*, *Deutzias*, *Philadelphus*, *Syringa*, *Forsythia*, and *Jasminum*. All of these should have their place. Last, but not least, there is the *Eucryphia pinnatifolia*, to me the most beautiful of all shrubs, but which is rarely seen. There are hundreds which might be named, but I have purposely confined myself to mentioning some which may be grown easily by all in almost any locality.

There is another important point, that of artistic grouping. In some the artistic sense is natural, in others it is only developed by careful study.—*Gardening Illustrated*.

AUTUMN PRUNING OF ROSES.—The removal of old growths after they have blossomed is a practice that may well be considered in the case of those sorts that flower once in a season only. If left till the usual Spring time of pruning these growths have only served to cramp and stifle the tree meantime, and therefore it will at once be seen that by taking away anything which prevents light and air is not encouraging to young, vigorous stems, which in respect to the Summer-flowering class is the style of growth desirable for a satisfactory display the following year.

The novice in Rose culture has only to first be satisfied as to what is a once-blossoming variety to know what to operate upon, and without naming a lot of sorts, American Pillar, Crimson Rambler, and Dorothy Perkins, three generally well known, may be mentioned as the class referred to. There are, of course, many of the type usually grown as climbers, pillar-trained either alone or in groups. It pays to thoroughly overhaul these specimens at the present season. By doing this we not only assist the growth that is wanted, help it to become strong but much that is of a filthy nature, insect-covered and so on, is removed at the same time. Each plant or tree may have all its fastenings removed, then thinned and re-tied. It is easy to distinguish between those growths that have flowered and those which have not; it is the former we do not retain.

Other Roses, that is, the Autumn as well as Summer flowering ones, may in many instances be assisted by a little thinning just now, dwarf bushes, those of standard form and all. Here and there stems may strike out in a sucker-like form and quite out-distance the rest on the plant. Shorten such that they do not take too much of the life of the bush. If not done now this becomes necessary the following Spring, and meantime something is done to balance the growth and provide ample new and side branches.—*Gardening Illustrated*.

AIKANETT ANTHUS ITALICA.—We would now bring out a mass of this beautiful blue-flowering plant, which has now become one of our principal subjects for lighting up the borders during a large part of Summer. It is in bloom long before the charming Larkspurs, and forms little forests of growth, which in its turn becomes a maze of loose sprays covered with myriads of intense blue flowers (gentian-blue is the description given to the deepest colored forms by many enthusiasts). Then we have that exquisite pale blue form known as var. *Opal*, which

is still in flower at the present time. It is a most interesting and beautiful plant, and is well worth growing. *Illustrated*.

TREATING THE SOIL FOR RHODODENDRONS.—Now, who does not love Rhododendrons, but finds that in his soil they will not grow? Dr. F. V. Colville of the United States Department of Agriculture seems to have solved the difficulty by the addition of aluminum sulphate to the soil. The old plan was to add old leaves of an acid nature to the soil or to water with a solution made from certain barks, but this claims to stimulate the growth of certain varieties as much as 250 per cent. The experiments have been in progress for some years and Azaleas, Kalmias and Heaths are also benefited.

For years I have preached the immense value of humus in the soil and how essential it is in the drought of South Africa, but

retaining qualities.
100 lbs. dry sand can hold 25 lbs. water.
100 lbs. clay can hold 50 lbs. water
100 lbs. Humus can hold 190 lbs. water.
In addition it promotes a chemical action or reaction which makes available to the plant food substances in the soil which are unaffected by other agents and this apart from its own great value as plant food. Therefore, to save your watering and to grow the

poor, sandy nature, where Rhododendrons will make plenty of roots, but which require the addition of some form of nourishment. Mulching with short grass or leaves will in a great measure do this, as it is not nitrogenous food that these Evergreens require, but rather decayed vegetable matter. Mulching, too, will sustain and promote freedom of growth by helping to retain moisture, and it should be remembered that Rhododendrons are moisture-loving subjects; they really require a large amount of water when in full

CASTANOPSIS CHRYSOPHYLLA.—This interesting evergreen California—is carrying an unusually heavy crop of fruits this Summer. These resemble clusters of small, Sweet Chestnuts, comprising burs, surrounded with spines, enclosing the edible nuts which germinate freely and provide a means of increase.

Though recorded as being first introduced in 1844, the Golden-leaved Chestnut has not been planted freely in Britain. In California trees exceeding 100 feet are on record. With us, at first, *Castanopsis chrysophylla* forms a shrubby bush, but, with attention to the leading shoot, and some thinning of the branches it becomes in time an attractive tree. The popular name refers to the color of the under-side of the leaves. The present abundant fruiting may be traced to the hot Summer of 1921, for the flowers of 1922 produced the fruits which are maturing at the present

COMPOST FOR BULBS.—Early Narcissi, Roman Hyacinths, and Tulips will soon require potting or boxing if flowers are to be available for the month of November and on through the Christmas time. The amateur cultivator often finds it difficult to obtain a suitable compost and so pots his bulbs in a quite unsuitable mixture. A north-country gardener once said to me: "I can grow bulbs in pure leaf-soil without going to any extra

but he favored leafsoil more than any other ingredient. I have sown many thousands of bulbs in pots and boxes since those days and have found a mixture of leaf-soil two-thirds, old loam one-third, and a fine sprinkling of sand to be a splendid rooting medium for all early bulbs.—*Gardening Illustrated*.

SPIRÆA TRICHOCARPA.—This new Spiræa is a first-rate shrub—in fact, one of the best of a useful if overcrowded genus of hardy, woody plants. It is a native of northern Korea, where it is a spreading bush about a yard high, but under cultivation it promises to grow to double this height. The shoots are angular, with prominent Winter buds, rigid and arching, forming a compact bush. A few hairs are present on the flower-stalks and carpels, otherwise the plant is glabrous. The short-petioled leaves are grass-green above, pale below, oblanceolate to elliptic-lanceolate, from 1½ to 2½ inches long and from ½ to 1 inch wide, often broadest above the middle, narrowed to the base, with a few short teeth at and near the apex. The flowers are white, scentless, flat, above ½ inch across, with emarginate, suborbicular petals; they are borne in rounded or dome-shape, 3 to 5 inches broad, corymbose clusters at the ends of short lateral leafy shoots.

This new Spiræa was discovered by T. Uchiyama in 1902, and subsequently named by Dr. Nakai. It is not uncommon in northern Korea, and especially on the Diamond Mountains, where it grows alongside streams and on cliffs. It was on these mountains that I found it in the Autumn of 1917, and sent seeds to the Arnold Arboretum. A good stock was raised, and this year plants have blossomed freely and shown the garden value of this acquisition. The plant has proved perfectly hardy in Massachusetts, and is as floriferous as any member of the genus. It is in full beauty of blossom when the flowers of *S. Henryi* are passing and before those of *S. Veitchii* open.

There are really too many Spiræas in cultivation, and for garden purposes the genus needs a thorough weeding. Recent plant introduction work in the Orient has added not a few species that have no particular claims as ornamental plants, but as compensation has given us some that are really superior to any other species. The hybrid *S. van Houttei* is not surpassed by any Spiræa, and in eastern North America is a favorite hedge plant. It flowers early, and is followed by *S. Henryi*. These two, with the new *S. trichocarpa* and the late-flowering *S. Veitchii*, are in my opinion, the finest of the true Spiræas with white flowers.—*E. H. Wilson, in Gardeners' Chronicle (British)*.

WHORL FLOWER (MORINA LONGIFOLIA).—This handsome plant does not appear to be so well known as it deserves, yet it is one of the most pleasing, distinct, and attractive plants now in bloom. The handsome spiny, polished leaves are conspicuous in themselves, and appear in graceful rounded clusters, from which arise the stout flower-spikes. The flowers are white and cerise, and abundantly produced in tiers upon the 2-foot to 3-foot stems. The Whorl Flower is a singularly attractive and pretty plant, unusually so during its period of bloom, and the effect of a group in bloom at the present time is decidedly good. It calls for no very special culture, and flourishes in any ordinary border soil, but is a lover of sunshine. Those who have not yet grown this distinct plant should certainly give it a trial.—*Gardening Illustrated*.

FRAGRANT TULIPS.—As the season for ordering bulbs is at hand, lovers of sweetly scented flowers should not overlook the Tulips. There may be several other varieties with which I am not acquainted, but the following three are very good, for, in addition to their delicious perfume, they are excellent for bedding and other purposes.

La Merveille is a characteristic Tulip and very sweet; the flowers are of terra-cotta color and produce a pleasing effect in groups and also when lightly arranged in vases. *Gesneriana lutea* grows rather taller than *La Merveille*, and its flowers are bright yellow, sweetly perfumed and most useful for cutting. *Ellen Willmott*, soft, creamy yellow, is also a very useful Tulip, apart from its sweetness.

For room decoration the flowers are best cut before they are fully open; in fact, I usually cut them when the flowers are just at the point of opening. There are numerous Tulips with charming colors, but few possess fragrance.—*Gardeners' Chronicle (British)*.

THE MEADOW SAFFRONS.—The term of Meadow Saffrons, are frequently called in error "Autumn Crocuses," whereas they are distinct from the true Crocuses of Autumn, and the flowers less refined. Yet they are worthy a place in the garden of hardy flowers, because of their beauty and value at a season when low-growing bulbous plants are scarce, and as helping to redeem the front of the border of perennial plants from some of the dullness caused by there being few hardy perennials of dwarf habit in bloom in late Autumn. They are also desirable for growing in grass or in the wild garden, although they should not be planted in places to which cattle have access, for the leaves of *Colchicum*

autumnale have been known to poison cattle which have browsed upon them, and probably the other species would have the same effect where such animals have access to the foliage, which develops in Spring. The chalice and cups of some of the Meadow Saffrons are very beautiful, and, as the foliage seems immune to the attacks of rabbits, their utility is obvious in certain places frequented by these animals.

The Meadow Saffrons have pleasing flowers, supported on long tubes, and it is desirable to grow them through dwarf herbage, which not only preserves the blooms from being splashed through heavy rains, but it relieves the bareness of the flowers when on uncarpeted ground. The plants will grow in any soil, but have a preference for ground which is not too light and is fairly moist. They do well on light, dry soil, but they do not attain the large size of those grown in richer earth.—*Gardeners' Chronicle (British)*.

Brief Horticultural Jottings

The rubber situation promises to be acute in a few years, according to rubber men, since not enough is being grown in the tropics to supply future demands, and much of that is now under foreign control, notably British. To stimulate research, Congress recently appropriated \$500,000 for developing a domestic supply. Plantations in the Philippines have been proposed, but owing to the fact that cheap contract labor, which is not permitted in these islands, is a vital necessity to the production of rubber in competition with foreign countries which permit it, and that such plantations could not be made productive in time to be of aid in the expected famine, the idea will doubtless be abandoned. Horticulturists, however, are giving the plan close attention. They are investigating the possibilities of at least two native plants for the production of rubber. One is the staghorn or hairy sumac, and the other is the ordinary milkweed. Both have a thick, white gummy sap, which forms a sticky, rubber-like mass on drying. Both can stand cold, something which no rubber plant can do.—*American Florist*.

At the seventy-fifth meeting of the board of directors of the United States Chamber of Commerce held in Washington, the following action was taken: The executive officers were authorized to request the appropriate officials of the national government to investigate the policies and actions of the Federal Horticultural Board with a view to lessening the severity of the restrictions imposed by that board in administering the plant quarantine act.

Apple growers of the upper Hudson River Valley are concerned over the appearance in their orchards of a pest known as the thorn and apple skeletonizer, whose destructive proclivities have been felt hitherto in the counties nearer the metropolis. Pomologists are finding difficulty in battling with the scourge because of the rapid flight of the moth which lays the eggs that ultimately develop into leaf-destroying caterpillar. It was finally identified as the skeletonizer, whose ravages in Europe had cost apple growers fortunes. Efforts to check its spread have not been successful. This newest of scourges to worry the apple grower is no stranger to portions of Connecticut, Vermont, Massachusetts and New Hampshire, where it had gained a foothold before the seriousness of its ravages was understood. As in insect invasions, spraying with arsenate of lead has been found helpful, though the gradual increase in the territory in which the plague is found indicates lack of thoroughness in the use of insecticides. Frequent and thorough spraying should be the policy of every apple grower.—*N. Y. Herald*.

To Owners of Country Estates

The Association of Gardeners of the United States, a Society of the Gardeners of the United States, has been organized in order to provide a medium for the exchange of information and to cooperate in the interests of the country estates.

Owners desiring the services of gardeners, thoroughly versed in all phases of the profession and qualified to assume the responsibilities the position calls for, as superintendent or gardener, should apply to this department.

The association numbers among its sustaining members, the owners of the prominent country estates in America.

The association makes no charge for any service it may render to

National Association Of Gardeners

Secretary's Office, 286 Fifth Ave., New York

The aims of the association are to elevate the profession of gardening by improving conditions within it.—To cement a closer bondship among all engaged in, and interested in, gardening—to create a greater confidence between employer and employee.

Co-operating with the Massachusetts Agricultural College, the association conducts a course in training young men for the profession, whereby they obtain theoretical knowledge as well as practical experience.

THE 1923 CONVENTION Pittsburgh's Welcome to the Gardeners

The opening session of the twelfth annual convention of the National Association of Gardeners convened at two-thirty o'clock on Tuesday, August 14, 1923, at the Fort Pitt Hotel, Pittsburgh, with Manus Curran of Sewickley, Pa., presiding as temporary chairman. In calling the convention to order, Mr. Curran asked the assemblage to rise and observe silence while George F. Stewart of Waltham, Mass., offered an invocation in memory of our late President, Warren G. Harding.

After the invocation, Mr. Curran introduced H. M. Irons, City Solicitor, who in the absence of the Mayor, represented the City of Pittsburgh and on whose behalf he extended the official welcome. While Mr. Irons stated that Pittsburgh is more generally recognized as an industrial center and would have much in that respect to show the gardener, horticulturally it would probably not measure up to some other cities they had visited. Nevertheless, he believed the gardeners would find much of interest in Pittsburgh's parks and on the beautiful estates in its out-lying districts. Mr. Irons admitted his slight knowledge of gardening, though, he could, he said, distinguish between a rake and a hoe and considered gardening a most healthful recreation and its profession one of the noblest, one full of inspiration which does much to uplift the humdrum existence of mankind. He added that an organization, such as the gardeners' national association, could find many opportunities to take part in civic activities, tending towards community improvement.

E. J. McCallum, representing the Pittsburgh Chamber of Commerce, who was the next speaker introduced, after welcoming the gardeners on behalf of the organization he represented, elaborated on the suggestion of Mr. Irons that the gardeners interest themselves in civic affairs. He spoke of the home gardens in which he believed interest should be revived to make them as important factors today as they were when they were known as "war gardens," emphasizing their value in food production which is again being restricted because of labor shortage. Mr. McCallum also stated that no more healthful recreation could be found than that which may be derived through gardening, for young and old.

Robert P. Brydon of Cleveland, Ohio, vice-president of the association, in responding to the addresses of welcome by Mr. Irons and Mr. McCallum, said: "We are here today for several purposes. We are assembled here in convention to discuss the problems which are of interest to ourselves, to discuss ways and means for bettering our conditions, but we are also here to see what the City of Pittsburgh has to offer us. We are here to see your buildings, your industries, your parks, your private estates, anything that will be of general interest to our profession. We are not only interested in gardening, but interested in everything else. On the other hand, it has occurred to me that it may be possible for us to leave something with you. In 1919, the National Association of Gardeners met in Cleveland. The inspiration that went out from that meeting created one of the finest and best movements in school gardening in the history of the United States. As a result of that convention, Cleveland has the finest school gardening course and greenhouses for the purpose; it has also a fine nursery; it teaches propagating, growing of plants, marketing, and everything that pertains to that line. As I have said, the inspiration has come from our association. Now is it not possible for us to leave something like that with the City of Pittsburgh? Is it not possible for you to get something from us so that we may feel that we have come here for some purpose, to give as well as to receive?"

Mr. Curran next introduced John C. Slack, a member of the Garden Club of America and of the Garden Club of Allegheny County, who bore greetings and welcome. Mr. Slack is a man well versed in the art of gardening and botany. In welcoming the gardeners to Pittsburgh on behalf of the organizations which he represented, Mr. Slack said: "In this day of sordid, narrow, self-interest and strife for advantage in almost every relationship of life, the devotion shown by each of you to the promotion of the beautiful, and the wider enjoyment of it, has formed a tie and a fraternal spirit with the Garden Club members, which has brought to them joy and happiness heretofore unrealized in the lives of many. You are truly missionaries, working in a fruitful and promising field, with sincerity and singleness of purpose in the work, and forgetful of the sordidness and commonplace in life,—forgetful of mere personal aggrandizement,—approaching your work in a spirit of the creative artist, enjoying the gratification of a new contribution to beauty which you so generously give to the world without thought of reward, and thereby bettering and uplifting those about you. Because of all this, the Garden Club members feel that they are led and stimulated by you to work together for the betterment of the world, and are first to acknowledge a debt of gratitude and appreciation due to you, by which they have so wonderfully profited. I am also directed

to tender on behalf of the Garden Club members the freedom of their gardens, and to deliver to you the heartiest invitation to visit them."

President Barnet also received a message from Mr. Samuel Sloan, president of the Garden Club of America, as follows: "May I send you all my best wishes for a successful meeting, and my congratulations for what the association has accomplished in the past."

In responding to Mr. Slack's greetings, William N. Craig of Weymouth, Mass. said: "It was a delight to listen to the remarks of the previous speaker. He represents the Garden Club of America, a club which has done more to stimulate, to uphold, and to advance horticulture than any organization I know anything of in recent years. It was the ladies who planned and started and are the bulwark of that body. A poet has well said the following:

Where is the man who has the power and skill
To stem the torrents of a woman's will,
For if she will, she will, you may depend on't,
And if she won't, she won't, and there's an end on't?

"We would have but little horticulture, very little floriculture in America but for the ladies, God bless them! You will find in any part of the country you may reside in, that the men, the bulk of them, are too busy amassing riches to think of the finer arts of horticulture and floriculture, but we are advancing, and the Garden Club of America, working in combination with the various florists' and gardeners' clubs, and this association and other bodies, does a great deal to stimulate horticulture in its best sense. I have great hope of any country where the children in the schools are taught nature studies and where horticulture and the love of horticulture are inculcated in their veins while young. Shakespeare has also well said that 'Gardening is an art that doth mend Nature, change it rather, but the art itself is Nature.' And can you think of any occupation in the world more interesting, more refining, more spiritual than gardening?"

"The Garden Club of America has done more than we appreciate in bringing together the estate owners and the gardeners. Gardening is a fine art which requires a vast amount of care and forethought, ladies and gentlemen. The gardeners are oftentimes not sufficiently appreciated, but since the advent of the Garden Club of America better relations have existed between the employer and employe, and the growth of this Garden Club, with the continued growth, as I hope, of our association, will still tend to foster and uphold the great profession of gardening, the advancement of our country, and the making of a more beautiful America."

Following Mr. Craig's remarks, Mr. Curran turned the meeting over to President John Barnet who presented his address, (It appears on page 207 of the August issue) after which Mr. Barnet introduced George H. Wirt, Chief Forest Fire Warden of the State of Pennsylvania. Mr. Wirt addressed the convention on the subject of forest conservation. (His address appears on page 226 of this issue.) In concluding, Mr. Wirt referred to the remarks of a previous speaker who laid the credit of the organization of garden clubs to the ladies. He then asked if the gardeners had ever stopped to consider who really was the first gardener, suggesting that if they had their Bibles with them, they read the first and second chapter of Genesis. "It was not Adam, but some one before. God planted the first garden and placed man in it. Then when reading, very carefully note who was responsible for the second gardener losing his job. Now, thanks to the first Gardener, He has instilled in the minds of our women folks, the very right-idea that we come back to God through Nature, and they are doing the gracious act when they help you and me to find a place in the sun raising garden, making things beautiful and making ourselves worthwhile," said Mr. Wirt.

Thomas W. Head of Red Bank, New Jersey, thanked Mr. Wirt for his illuminating address and recalled an address he had heard sometime ago by Congressman M. L. Davey in regards to our forests and how they were becoming denuded, and stated at that time he thought what a wonderful opportunity the gardeners had. Mr. Head admitted, however, that he did not realize then, and he believed that not many others realized, how much work there is to be done along this line. Mr. Wirt's address showed the work before them and opened the way.

After several announcements were made by President Barnet, referring to the business sessions and the entertainment features of the convention, the opening meeting was adjourned.

WEDNESDAY MORNING SESSION

The second session of the convention opened at nine thirty o'clock on Wednesday morning, August 15, with President John Barnet, presiding, who called upon Secretary M. C. Ebel for his annual report (It appears on page 208 of the August issue) and for the Secretary's financial statement which follows:

Secretary's Financial Statement

New York, N. Y., August 1, 1923	
Cash on hand, Sept. 1, 1922	\$1,033.83
Received for 1923 Dues	105.00

Received for 1922 Dues.....	620.05	
Received for 1923 Dues.....	3,045.00	
Received for 1924 Dues.....	10.00	
Received for 92 Sustaining Memberships.....	920.00	\$5,733.88

Payments to Treasurer, Voucher No. 226, Slips Nos. 1-19	\$5,733.88
Appropriation voted to Secretary for office rent, assistant's salary, printing, postage, stationery, telephone, telegraph, and other expenses pertaining to the operation of the Secretary's office, at the Boston, 1922, convention, and paid by the Treasurer.....	\$3,000.00

M. C. EBEL,
Secretary.

Pittsburgh, Pa., August 14, 1923.

We have completed our audit of the accounts of your Secretary up to August 1, 1923, and are pleased to report that we find the statement as rendered above to be correct.

GEORGE F. STEWART,
ROBERT P. BRYDON,
JAMES STUART,
Auditing Committee.

It was regularly moved that the Secretary's report and financial statement be received and placed on file.

President Barnet then called on Treasurer Montague Free for his report which follows:

Treasurer's Report

Brooklyn, N. Y., August 1, 1923.

Receipts.	
Balance in Bank, Sept. 1, 1922 (Gen'l Fund) ..	\$2,318.08
Balance in Bank, Sept. 1, 1922 (Res. Fund) ..	397.28
Deposit voucher No. 226, Slips Nos. 1-19 (Gen'l Fund)	5,738.88
Interest, General Fund	19.89
Interest, Reserve Fund	16.84
Interest, Liberty Bond	42.50
	\$8,533.47

Disbursements.

Vouchers Nos. 406 to 431 as follows:	
The Multi-service Bureau, Inc. Voucher No: 406	\$3.75
Dieges & Clust, medals	14.00

Chronicle Press, Inc., for advertising Voucher No. 409	20.00
Secretary, for office expenses Voucher No. 410	116.25
Secretary, honorarium (for 1922)	1,000.00
The Convention Reporting Co. Rept. Boston Convention	85.40
Secretary's Appropriation:	
Sept. 1, 1922 to Aug. 31, 1923	\$3,000.00
Less vouchers Nos. 406, 408, 409, 410	240.00
	2,760.00
American Surety Co., premium on treasurer's bond	7.50
The Chronicle Press, Inc., subscriptions.....	1,399.50
Treasurer's postal expenses	1.28
Exchange charges40
Member's check return 'no funds'.....	5.00
	5,513.08
Balance in Bank, Aug. 1, 1923 (Gen'l Fund) ..	2,143.27
Balance in Bank, Aug. 1, 1923, (Res. Fund) ..	877.12
	3,020.39
	\$8,533.47

Investments.

Third Liberty Loan Bond	\$1,000.00
	MONTAGUE FREE, Treasurer.

Pittsburgh, Pa., Aug. 14, 1923.

We have completed our audit of the accounts of your treasurer up to Aug. 1, 1923, and are pleased to report that we find the statement as rendered above to be correct.

GEORGE F. STEWART,
ROBERT P. BRYDON,
JAMES STUART,
Auditing Committee.

It was regularly moved that the Treasurer's report be received and placed on file.

As Secretary Ebel had no committee reports or communications to present at the time, the business proceeded to the consideration of the next meeting place.

Spring Meetings at Cleveland and at Boston, 1924

An invitation received from the Cleveland Branch to hold a Directors' meeting and a Spring meeting of all members during the week of the National Flower Show the latter part of March, 1924, was favorably acted upon. It was also decided to maintain an Information Booth at the National Flower Show to enable country estate owners to become better acquainted with the activities of the association, and incidentally to promote a campaign for an enlarged sustaining and active membership.

On the invitation of the Boston Branch, it was also favorably voted to hold a Spring meeting in that city during the National Orchid Show which will occur in May, 1924.

Awarding the Association's Gold Medal

It was proposed to award the association's gold medal at the National Flower Show at Cleveland and at the National Orchid Show at Boston, which at once provoked quite a discussion, many of the members urging that the medal should not be awarded except for something well merited as a horticultural achievement. It was pointed out that the gold medal had been awarded but four times in twelve years: to George H. Pring of St. Louis, Mo. for a new water lily; to Adolph Lewisohn of Ardsley, N. Y. for the most meritorious exhibit at an International Flower Show, New York; to George F. Stewart of Waltham, Mass. for a new *calceolaria*; to William H. Waite of Rumson, N. J. for a meritorious exhibit of new dahlias. The decision was finally reached that the gold medal be offered as an award for a meritorious effort in horticulture, the conditions of the award to be left to the judgment of committees which will be appointed by the Cleveland Branch and by the Boston Branch.

1924 Convention

Washington, D. C., Newport, R. I., and Detroit, Mich., were proposed as meeting places for the 1924 convention. It was voted to leave the final decision to the Board of Directors at its meeting to be held at Cleveland next Spring.

Nomination and Election of Officers

The nomination and election of officers for 1924 resulted as follows: For President, Robert F. Brydon of Cleveland, O.; for Vice-President, James Stuart of Mamaroneck, N. Y.; for Secretary, M. C. Ebel of Summit, N. J.; for Treasurer, Montague Free of Brooklyn, N. Y.; three Trustees for the state of New Jersey, D. L. Mackintosh of Alpine, N. J., Percy Hicks of Oceanic, N. J., and Donald Crighton of Convent, N. J.; two Trustees at large John Barnet of Sewickley, Pa., and William E. Fischer of Chagrin Falls, O.

Appointment of Committees on Resolutions

President Barnet appointed H. E. Downer, Arthur Brown, and Robert De Schryver to consider recommendations made in the Secretary's report and to submit resolutions; Committee on Resolution on Deceased Members, David Fraser, Ernest B. Palmer, and George F. Stewart; Committee on Final Resolutions, William N. Craig, D. L. Mackintosh, and James Stuart.

Following a Round Table discussion recess was declared.

WEDNESDAY AFTERNOON SESSION

Local Branches

The following delegates reported as representatives of the local branches: F. L. Balogh for the Cleveland Branch; William N. Craig for the Boston Branch; Thomas W. Head for the Monmouth & Elberon, N. J. Branch; John R. McCulloch for the Nassau Co., L. I. Branch; Manus Curran for the Western Pennsylvania Branch. All the delegates reported progress and growing interest in the branches, stating that they were of the opinion that the branches would, in time, become a strong co-operative factor in the administration of the association. Questions pertaining to the individual policies of the branches were asked and answered, such as what actually comprises the membership of a local branch, the duties of its officers, methods of defraying expenses. Experiences of various branches were related, showing that each branch has its self-government. Some of the members present declared that after the interesting discussion, they were prepared to return to their homes and to endeavor to organize local branches in their districts.

The Official Organ

Some discussion arose regarding the status of the official organ in its relation to the professional gardener, some members contending that it should be more representative of the gardener himself. It was explained that while it is the policy of the *GARDENERS' CHRONICLE* to cater to the gardeners, it also realizes

that it has a mission to perform in presenting their cause to the outside world, and thus acquaint the public with what a trained gardener is and the recognition he is entitled to. The aim of the official organ is to interest the employers in it and have them read what the gardeners are striving for. That is the way in which the association is securing recognition for the gardeners. George F. Stewart spoke for the *GARDENERS' CHRONICLE* and stated that there is a phase of the subject which had hardly been touched upon. He said: "Our National Association of Gardeners is an organization to establish a better relationship between employer and employe. I find from letters received during the little time I have been writing for the paper that this is being done by the *CHRONICLE*. Employers have written me and told me that they never knew what a gardener really was until they began to read the *CHRONICLE*; that they never knew that a gardener really knows as much as he does. Now the *CHRONICLE* is doing just what our national association is here for. And furthermore, since writing these notes, a better relationship has been established personally between my employer and myself. He became a sustaining member and received the paper, and not being very well posted on many things, pertaining to gardening, he reads the paper as do also his wife and daughter. Personally this has been a good thing for me."

On Training Young Men

A communication from the Pennsylvania State College was read which invited the association to co-operate with it in establishing a course for training young gardeners, somewhat similar to that now in force at the Massachusetts Agricultural College in co-operation with the association. The Pennsylvania State College advised that it expects to acquire control of a large private estate in Pennsylvania which has been willed to be devoted to the training of young men in gardening. This estate is said to contain one of the finest collections of rare trees and shrubs in this country, which makes it especially valuable for the purpose for which it has been set aside. The association voted to give its whole hearted support to the Pennsylvania State College in any movement it may undertake to train young gardeners. The question arose as to whether it will ever be possible to make the profession of gardening sufficiently attractive to the American youth, the contention being that the American boy seeks something more lucrative as his life work. This argument, however, was disproved by the interest the American youth is already manifesting in the gardening profession, since the means have been provided to acquire theoretical knowledge as well as practical experience. The American youth realizes the advantages of the environment connected with the vocation of gardening and the broad fields of endeavor which the future of the gardening profession in America offers. Whenever the subject of the future prospects of gardening in this country is discussed among gardeners, there is always found to be a diversity of opinion, but at the convention, the optimistic views out-weighed the pessimistic ones. While it was agreed that not many gardeners will ever attain wealth through their vocation, it was conceded, however, that the gardener holding a comfortable position, is fully as well situated in life as the followers of many other professions, not in remuneration only but in other ways also. While the ability of the gardener has not been recognized in the past, as it should have been, conditions are changing and the capable men of the profession find that their efforts are being more appreciated today than they were heretofore.

Committees on Resolutions

President Barnet called upon the committees on resolutions to present their resolutions, which were submitted and accepted as follows:

Resolution on Professional Ethics

WHEREAS it seems to be the thing to do in these days of business turmoil, whenever a vocational convention meets, to pass resolutions glorifying itself while criticizing an affiliated vocation for its shortcomings,

BE IT RESOLVED, That the National Association of Gardeners strongly protests against the attacks aimed at the gardener and his profession from time to time relating to professional ethics. The association does not claim that all gardeners are as yet immune from temptation but it does claim that the members of the gardening profession are not as sorely afflicted with corrupt practices as are the followers of some of the other vocations.

BE IT FURTHER RESOLVED, That the National Association of Gardeners confirms the action taken at the Cleveland convention in 1919, endorsing all standards which tend to elevate the professional ethics and business methods in all fields of endeavor.

H. ERNEST DOWNER,
ARTHUR BROWN,
ROBERT DE SCHRYVER.

Resolution on Rumor-Mongers

WHEREAS, the Secretary has directed attention in his report to the injury at times done to fellow members through the circulation of false rumors,

BE IT RESOLVED, That the Secretary be instructed, whenever a rumor may be brought to his attention concerning a member, to immediately institute an investigation and if this rumor is unfounded and it has been found to have originated with a member of the association, to act in accordance with Article II, Section 8, of the By-Laws, the Executive Board authorizing the Secretary to call together a committee of three members of the Board as its authorized committee to confer on what action shall be taken.

H. ERNEST DOWNER,
ARTHUR BROWN,
ROBERT DE SCHRYVER

Resolution on Deceased Members

The members of the National Association of Gardeners assembled in their annual convention at the Fort Pitt Hotel, Pittsburgh, August 15, 1923, wish to express their sincere sorrow at the loss their ranks have sustained in the death of their fellow members, Frank J. Dupignac, William Grey, M. J. O'Brien, Douglas Smith, E. Stuart Smith, Frank E. Ehrler, George Jacques, J. Carroll Hawkes, John S. Hay, and wish to express their sincere sympathy to the families and those near and dear in the loss they have sustained, a loss we equally share.

RESOLVED, That a copy of these resolutions be forwarded to the families of the deceased members and spread on the records of the association

GEORGE F. STEWART,
DAVID FRASER,
ERNEST E. PALMER.

Final Resolutions

The members of the National Association of Gardeners assembled desire to extend their thanks and appreciation to all those who have contributed to the success and enjoyment of our annual convention here in Pittsburgh.

We specially desire to tender our thanks to the Western Pennsylvania Branch for the splendid program and entertainment provided by it; to the various local committees under the able chairmanship of Manus Curran, who have added so much to make our visit to Pittsburgh a most enjoyable one; to the ladies' committee which has specially provided entertainment for the visiting ladies to the convention; and to the Pittsburgh Florists' and Gardeners' Club for the enjoyable reception tendered to us.

Finally we request that Mr. Curran send a personal letter of thanks to all who cordially invited us to visit their estates.

WILLIAM N. CRAIG,
JAMES STUART,
D. L. MACKINTOSH.

President Barnet then announced the business sessions of the convention adjourned.

ENTERTAINMENT FEATURES

Illustrated Lecture

On Tuesday evening at the Fort Pitt Hotel, an illustrated lecture was given by E. J. Cogshall of the Carnegie Institute on "Hunting Big Game in the Rocks." The subject was very interesting and unusual, the illustrations showing the excavation of the mammoth fossils of pre-historic days from the rocks in the desert of Utah, and the assembling together of the parts in the laboratory of the Institute. Pictures were also shown of the covering of these fossils with rubber skins to give some idea of their appearance when they inhabited the earth thousands of years ago.

The Annual Banquet

On Wednesday evening, the annual banquet was held at the Fort Pitt Hotel. The banquet hall was very artistically decorated with palms and gladioli, presenting a pleasing effect. President Barnet, after welcoming the guests, requested George F. Stewart to offer a blessing after which the gathering sang "America." He then introduced Ira S. Harper of Pittsburgh who presided as toastmaster and performed his task in a witty and clever manner, keeping the banqueters in good humor throughout the evening. Mr. Harper called on Robert P. Brydon, vice-president of the association and president-elect, as the first speaker, who referred to the honor which had been conferred upon him earlier in the day and assured the members that he will carry on the affairs of the association to the best of his ability, and will endeavor to make progress his watchword. James Stuart, vice-president-elect, also expressed his appreciation of the honor conferred on him and stated that he would, as in the past, continue to do his part for the welfare of the association. William N. Craig paid his respects to some of the pessimistic views voiced during the business sessions regarding the future of the gardening profession when

he said that gardeners are the most comfortably situated men on earth, for they derive the pleasures of an estate without having to pay the bills. He expressed his opinion that gardening is an excellent profession for young men to enter, as it is one of the fine arts. George F. Stewart said he was disappointed at his fellow gardeners in the view they held about the American boys and gardening, adding that the American boys will learn far more quickly, and use their faculties in a wider measure than "the pessimistic men from across the sea." He admonished his listeners not to worry over the future of gardening in this country, for man can not get away from gardening which is God's own occupation. D. L. Mackintosh had evidently exhausted himself on the more serious problems of life earlier in the day, so entertained the guests with some of his Scotch wit, contributing to the mirth of the evening. Jack Baxter proved so enraptured with his profession that he could not forget it even at the banquet table and spoke of the wonderful opportunities offered the gardeners as green-keepers of country clubs, that is, for those who know how. John R. McCulloch recalled the days of his arrival in this country in 1880, when he purchased a ticket for Pittsburgh and found himself in Chicago, and had to wend his way back to the former city, where he secured a position as a mill hand at the princely salary of \$33.20 a month, from which was deducted \$7 for board and room. Mr. McCulloch compared this salary with what the young men of today receive while securing their training. Andrew Rogers was reminded of the story of a doughboy who attempted to fill the place of General Pershing at a meeting when the General failed to appear as speaker of the evening. Noting the disappointment of the audience, some one called out, "Don't forget this young man went through h— for you. You ought to be willing to do likewise for him." Mr. Andrews requested his hearers to bear with him in what he was about to go through, adding that he enjoyed attending conventions for it afforded an opportunity of meeting old friends and making new ones. Thomas W. Head stated that a little comedy injected in life relieved its more serious side, and it seemed to him that it had been one comedy after another since his departure from home. Andrew Wilson upheld his reputation as a story teller and amused his listeners with jokes, novel and antique, possessing the cleverness of fitting his tales to individuals present. Mr. Wiseman mentioned the floral decorations appearing in some of the seedsmen's and florists' shops in Pittsburgh, showing the emblem "N. A. G." which had stirred the curiosity of the residents of Pittsburgh, as to what "NAG" meant, to whom it was explained that its real meaning is progressiveness. F. T. D. Fulmer, who was one of the oldest members of the association present, both in point of age and in membership, and had travelled the farthest distance to attend the convention, spoke of his pleasure in being able to be with his fellow gardeners and related some of his experiences in gardening in the past, comparing it with the progress of recent years. Neil McCallum spoke of the ancient history of flowers and ended his remarks with the words of Kipling—

"And only the Master shall praise us, and only the Master shall blame
And no one shall work for money, and no one shall work for fame,
But each for the joy of working, and each, in his separate star,
Shall draw the Thing as he sees It for the God of Things as They are!"

The banquet was concluded with the singing of "Auld Lang Syne." Throughout the evening, the famous "Dixie Lindsey Quartette" provided entertainment, and later furnished music for dancing.

Thursday's Automobile Tour

The convention party left the Fort Pitt Hotel in automobiles at nine-thirty o'clock, traveling over the Boulevard from which an excellent view was obtained of the mammoth steel mills; thence through the grounds of the University of Pittsburgh, and on to the East End, the beautiful residential section, where the grounds of the attractive homes were observed to be well landscaped and maintained in fine order. The automobiles passed through the estates of Andrew Mellon, Secretary of the Treasury, R. B. Mellon and D. M. Clemson, situated right in the city of Pittsburgh, and on to Schenley Park, where the visitors walked through the large conservatories, regarded as one of the best park conservatories in the country. The party then proceeded through West Park and continued on its way to Sewickley, passing through stretches of wonderful scenery en route. In Pittsburgh in front of the Carnegie Library, a "Welcome Convention" flower bed was noted, also a "Welcome Gardeners" flower bed at Schenley Park, and another at West Park, "Welcome N. A. G., 1923." Many of the seedsmen's and florists' windows were decorated and said it with flowers in welcoming the gardeners to their city.

Arriving at Sewickley Heights, the party went direct to the estate of Mrs. J. D. Lyon, where President Barnet is superintendent. No time was lost in gathering at the tables placed on the lawn, where a luncheon was served and enjoyed by all the

conventionists. During luncheon, a long distance telephone message was received by President Barnet from Mrs. Lyons, who had just arrived in New York from Europe, asking him to extend Mr. Lyons' and her greetings and to wish everyone an enjoyable time while on their estate. Mr. Mackintosh responded on behalf of the visitors and asked Mr. Barnet to convey to Mr. and Mrs. Lyons their appreciation of the cordial greetings and hospitality. On leaving this estate, the party drove through the grounds of the Allegheny Country Club, regarded as one of the finest of its kind in America, and then wended its way through the slopes of the Allegheny Mountains, commanding remarkable views of the mountain sides. The following estates were visited: W. B. Schiller (C. E. Norton, superintendent), N. B. Snyder (William Thomson, superintendent), B. F. Jones (George W. Brownhill, superintendent), Mrs. W. A. Laughlon (Henry Goodband, superintendent), Mrs. William Hemp (John Jones, superintendent), H. L. Mason (James Murphy, superintendent), Mrs. H. R. Rea (Alex Davidson, superintendent), Mrs. J. B. Oliver (Francis B. Reig, superintendent), Mrs. Halsey Williams and John C. Slack, after which the automobiles returned to Pittsburgh, arriving at the Fort Pitt Hotel about seven o'clock. The weather man had been most thoughtful, for the day had been cool and clear, and no smoke screen shrouded the views from the visitors at any time.

Reception to Gardeners

Thursday evening the Pittsburgh Florists' and Gardeners' Club tendered the convention party a reception in the English Room of the Fort Pitt Hotel. Tables were arranged for those who desired to play cards, while ample space was provided for those who preferred to dance. A splendid orchestra furnished music. Later in the evening a collation was served, and general good fellowship prevailed. On behalf of the club, William Thomson welcomed the guests, to which William N. Craig responded on behalf of the members of the association. Andrew Wilson also entertained with songs, dances and stories.

Viewing the Industrial Side of Pittsburgh

The first visit of the convention party on Friday was to the plant of the H. J. Heinz Company, where it was conducted by guides through the various departments, showing how the "pickles and preserves" are prepared. All enjoyed a short, but interesting, lecture on the preparation of the Heinz products, after which the party sat down to a nice spread, although it was not able to partake of all the "57 varieties." In the afternoon several hours were spent at the Westinghouse Electric Company's plant at East Pittsburgh, which proved most instructive in many ways.

Farewell Dinner

When the party returned to the hotel, a farewell surprise in the nature of a dinner was in store for it, served in the Dutch Room and tendered by the members of the Western Pennsylvania Branch. Manus Curran welcomed all in the name of the local branch, to which Robert De Schryver responded. Mrs. Jack Baxter accepted this occasion as an opportune time to thank the Ladies' Committee on behalf of the visiting ladies for the pleasant entertainment provided for them, and did this most appropriately. Mrs. William Thomson, chairwoman of the Ladies' Committee, replied in a fitting manner. The event was accepted by those present as a splendid finish to the altogether successful convention.

Ladies' Entertainment

The visiting ladies were well taken care of from the moment of their arrival at the Fort Pitt Hotel, where the Ladies' Committee, of which Mrs. William Thomson was the chairwoman, greeted them. At noon on Tuesday they became the guests of the Ladies' Committee at luncheon, after which they attended the opening session and in the evening the lecture by A. J. Cogshall. On Wednesday, the ladies were taken on a sightseeing and shopping tour of the city, with a luncheon arranged in their honor at one of the well-known restaurants, followed by a theater party, and returning to the hotel to participate in the annual banquet. On Thursday and Friday, they accompanied the male members of the convention party on the sightseeing trips.

SIDELIGHTS OF THE CONVENTION

The efficient manner in which Chairman Manus Curran conducted the opening session and the Parliamentary tact displayed by President John Barnet throughout the business sessions was a demonstration of how far the gardeners' ability extends. There appears to be no limit to it, for whenever gardeners gather together, someone may be found to cope with any situation, whether it be preaching, directing, arguing, or entertaining. Each year at the convention, we learn more and more what the capabilities are which professional gardeners possess.

After City Solicitor Irons handed the keys of the City of Pittsburgh (so to speak) to the visitors, he lauded the gardening profession and extolled the good the gardener is doing as a benefactor of mankind. He said that the rake and hoe hold more interest for him than a driver and putter, and that he finds more pleasure in hoeing a garden than in "plowing up" a golf course; that to him, gardening is a far healthier recreation than golf, which is rapidly developing into a "foot and mouth disease"—the golfer hoofs it over the course all day and argues about the game all night.

George H. Wirt admitted he knew the difference between a rake and a hoe, but he would not delve deeply into the subject and so find himself in the place of the minister who addressed his Sunday School class on the benefits to be derived from the great outdoors, saying that he was raised among the corn stalks. Upon questioning his scholars, "What would you call me?" the proverbial little Johnny replied, "Preacher, I'd call you a pumpkin."

Scotch wit seemed to be somewhat dulled during the opening session, but came into evidence during the business sessions and at the banquet. When D. L. Mackintosh attempted to introduce a little comedy during a strained moment at the Tuesday morning session, John R. McCulloch rose and protested that comedy should be prohibited whenever a meeting is found in a serious strain of mind. It might be added that the protestant was later converted and found himself a regular "sketch" before departing for home.

After the members had retired to their rooms from the banquet shortly after midnight, they were treated to a succession of loud explosions, which brought everyone to the windows to endeavor to discover what was about to befall them. Thomas W. Head, on noticing a reflection on the wall (which was caused by the sputtering of some trolley wires) concluded that a severe thunder storm was approaching and returned to bed, rejoicing that it had not arrived twelve hours later, when it might have caught the conventionists, partaking of a delicious luncheon on a Sewickley estate. From an adjoining room came the suggestion that someone must have set the mines off. Andrew Wilson, though his head appeared well out of the window, claimed he was not disturbed at all by the racket, for it simply reminded him of the good old days when the bowling tournaments were included in the convention programs. Our curiosity not being satisfied by any of the suppositions, we called the telephone operator, who informed us that the noise was due to the culmination of an Italian celebration on a hillside. Those bombs were certainly well charged!

As the automobile party on Thursday morning traveled through the streets of Pittsburgh in a line of over forty cars, composed of Pierce Arrows, Packards, and cars of similar make, furnished by employers of local members, some driven by liveried chauffeurs, and each bearing the banner of the National Association of Gardeners, the man in the street must have imagined that the association was allied with the moneyed interests. While this is not exactly so, nevertheless, every member in the line became imbued with a spirit of optimism over the promising prospects which the future holds forth for the profession.

That Pittsburgh possesses more than merely smoke and money became quite evident as the party motored through the extensive grounds of the University of Pittsburgh with its many magnificent structures devoted to learning. The Bostonians appeared amazed to find that Boston does not have a monopoly on culture.

When the convention party reached Mrs. Lyons' estate, President Barnet, who has the supervision of this beautiful estate, was observed on the lawn, attired in white flannels, which caused a young lady in the party to remark, "Why, that must be the owner." A little later when seated at one of the luncheon tables, she again saw President Barnet, this time assisting the steward hustling the waiters about, she remarked to her mother, "That man we saw was not the owner. He must be the butler." Had she noticed him a few minutes later, lecturing the waiters who had upset a tub of ice and rock salt on his beautiful lawn, which threatened its ruin, she might have guessed right as to his real identity.

After James Stuart had consumed his third helping of the bountiful luncheon, he recalled that no oysters had been served. This caused him to comment that the steward must be a Scotchman, for the Scotch despise oysters, as there is too much waste to them for the shells cannot be eaten.

George F. Stewart, who traveled from Massachusetts to the convention city by auto, accompanied by his sons (two American youths of whom he can be justly proud, who are following their father's profession) said that a long felt desire to see something of the West had been gratified, that crossing the Alleghenies was indeed wonderful, and that he expected almost any minute to see Macbeth and MacDuff step out of the wilderness for their mortal combat. F. T. D. Fulmer, hailing from Iowa, previously expressed

his gratification on being able to come East to attend the convention.

During the reception tendered by the Pittsburgh Florists' and Gardeners' Club, William N. Craig told the story of the Scotch gardener who awoke one morning to find that his wife lay dead beside him. Greatly startled, he jumped out of bed, rushed to the head of the stairs and excitedly called to the maid, "Mary, Mary, boil only one egg this morning!" Someone asked Mr. Mackintosh if he could beat that for Scotch thrift. Rising, he said he could only illustrate it by showing how very economical a Scotchman can be with the use of words when he had nothing to say—and then sat down.

After the visiting gardeners had had an opportunity to inspect the "Work Shop of the World," as Pittsburgh is sometimes called, and to inspect at first hand the conditions under which the mill hands labor and their home surroundings, they began to realize that their lot in life is not such a bad one after all, that their profession has much to offer which cannot be enjoyed in the heart of industrialism.

DIRECTORS' MEETING

A meeting of the Trustees and Board of Directors was held at the Fort Pitt Hotel on Tuesday forenoon, August 14, with President Barnet presiding. The following were present, H. Ernest Downer, Montague Free, James Stuart, D. L. Mackintosh, R. P. Brydon, Thos. W. Head, George F. Stewart, and M. C. Ebel.

There was considerable business brought before the meeting much of which was recommended to be submitted to the open convention for final decision. Different reports received showed that the association is making excellent progress and that it is commencing to bear the fruit of its early efforts; especially is this true regarding the organization and activity of the local branches, and the interest which the employers, the country estate owners, are manifesting towards the association was also noted to be increasing, as has been evidenced by the past few conventions.

JOHN W. JONES

John Wynne Jones, familiarly known to thousands of flower lovers throughout the country as the man who made Phipps conservatory, Schenley Park, famous for its beautiful flower shows, died in Mercy Hospital of bronchial pneumonia the day the convention of the National Association of Gardeners, of which he was a member, closed, and for the success of which he had striven hard before illness overtook him.

Shortly before the convention opened, he constructed a carpet bed design of flowers on a plot leading to the conservatory, embracing in it a welcome to the delegates. He went on his vacation for a visit to a brother in Toronto. On his return he contracted a cold that brought about his death.

He came to Phipps conservatory 30 years ago from New York and every year since then has given Pittsburgh a Spring and Fall show that experts say has never had a parallel. His hobby was Chrysanthemums and he created varieties of the flower that have had no equal.

He was born in Wales and was 64 years old. In addition to the national association, he belonged to, and was a former president of, the Pittsburgh Florist and Garden Association and the Botanical Society of Western Pennsylvania. Besides his brother Thomas, Toronto, he leaves his widow, one son, John W. Jones, Jr., a daughter, Helen W. Jones, and a sister, Mrs. James Smart, Carnarvon, Wales.

THE GARDENERS MARCH OF PROGRESS

The definite and commendable progress of the profession of gardeners along the route toward higher professional ethics and greater professional efficiency in common with other groups of commercial horticulturists, has been well typified of late in at least two widely separated cities. Reports of progress and of action aiming toward further development were naturally to be expected from the annual convention of the National Association of Gardeners that has just closed at Pittsburgh. The addresses of the president and secretary of the Association, thoroughly justify those expectations.

The interesting discussion of the gardener's position and prospects that took place at the convention of the Canadian Florists' and Gardeners' Association, and the still more significant forming of a gardeners' sub-section of that organization during the meeting, furnish further testimony to the increasing importance and growth of this branch of the horticultural profession. Perhaps the most gratifying phase of this whole subject is the clear indication of the increasing co-operation that is developing between the

gardeners themselves and the more commercial interests and representatives of the horticultural industry. With keener mutual understanding and greater harmony between these groups, the permanent welfare of both and the inevitable broadening of horticultural achievements are bound to result.—*Florists' Exchange*.

WHY NOT INCLUDE THE GARDENERS?

The truth of Christ, which alone can make men one and enable them to enter into the liberty which belongs to the sons of God, is being proclaimed not only from the pulpits of the land, but also from practically every platform where public questions are considered. Doctors and lawyers, bankers and educators, politicians and captains of industry, judges and statesmen are all heralds of the glad tidings which shall bring great joy to the people.—*Standard Union*, Brooklyn, N. Y.

Had the writer of the foregoing article attended the gardeners' convention and listened to the frequent Scriptural quotations in reference to applying them to our every-day life, he surely would have included the gardeners as heralds of glad tidings.

LETTERS OF APPRECIATION

The secretary received the following letter from an estate owner in Massachusetts:

"I am enclosing my check for \$10 as my sustaining dues to the National Association of Gardeners, which I am much pleased to have joined for I certainly think it is a most excellent thing. I want to take this opportunity to tell you how very satisfactory

— — — has been, and how grateful I am to you for recommending him. He has been with us for two years and a half and we are exceedingly pleased with him in every way. He is not only efficient, able and knows his work, but he has a sense of responsibility and a feeling for our interests which is very unusual. As his coming to us was entirely due to you, I am taking this opportunity to thank you.

I hope the Association is getting on well for it certainly fills a long felt want."

The secretary received the following letter from an estate owner in Ohio:

"Your letter of the 13th inst. at hand and contents noted. It is true that I have a new gardener, _____ and I think he is going to make a very good man. Since he belongs to your Association, you may be interested in knowing how I, personally, feel about him. He is a credit to your Association, a man who understands his business and attends to it strictly.

To please him I have no objection to becoming a sustaining member of your Association for I am interested in any organization which aims to elevate the standard of the gardening profession."

MONMOUTH & ELBERON, N. J. BRANCH

A meeting of the local members of the National Association of Gardeners was held on August 11 at the Elks' Club, Red Bank, N. J., for the purpose of organizing a branch of the national association. Thomas W. Head was elected chairman and Frank T. Edington, secretary. Mr. Head explained the advantages of a local branch and the opportunities which it gives to members to keep in closer touch with the activities of the parent society. After the organization, the members present engaged in some interesting discussions. Mr. Head was appointed to act as delegate of the branch to the annual convention at Pittsburgh, after which the meeting adjourned.

FRANK T. EDINGTON, Secy.

NEW MEMBERS

Sustaining: Arthur V. Davis, Millneck, N. Y. (Alexander MacKenzie, superintendent); Sigmund Stein, Hartsdale, N. Y. (William G. Ellis, gardener); Charles M. Schwab, Loretto, Pa. (Nathan Ireland, superintendent); Miss Mabel Choate, Stockbridge, Mass. (Robert Crighton, gardener); Charles K. King, Mansfield, Ohio (Earl Robertson, superintendent); S. C. Pirie, Sea Cliff, L. I. (Ross Gault, gardener); Mrs. Walter S. Mitchell, Pittsburgh, Pa. (Robert Ladner, superintendent); Mrs. A. D. Baldwin, Cleveland, Ohio; Mrs. C. A. Otis, Willoughby, Ohio (Hugh Mansfield, superintendent); Miss Belle Sherwin, Willoughby, Ohio (Luther B. G. Webb, superintendent); L. E. Sisler, Akron, Ohio (William Mailer, gardener). *Active:* Charles Lawrence, New York City; E. J. Sohmers, Syosset, L. I.; Allan Roberts, Grosse Pointe, Mich.; William S. Alt, Hyde Park, N. Y. *Associate:* Harold E. Leary, Donaldson M. Smith, Boston, Mass.; Edward A. Manda, West Orange, N. J.

Of Special Interest To You Would-Be Greenhouse Possessors

With greenhouses, as with autos and most other things, there are a certain few that are favorites. Year after year those same favorites have continued to be favorites. Such being the case, then, there must be certain very logical reasons for it. Reasons that will appeal to you quite as they have to others. Appreciating such, it's a wonder we hadn't thought long ago to bring these favorite greenhouses together and make a special little catalog of them. However, we have done it now. Done it in a most attractive way

that we are sure will appeal to you and your love of flowers and growing things. Five favorites are shown, among which unless we are greatly mistaken, you will find just the greenhouse that best suits your needs and fits your pocketbook. There are plenty of photos of both exteriors and interiors, besides plans and ample description. So complete is it, that without any further ado, houses have been purchased directly from it. Mayhap you will do the same. You are most welcome to a copy of this new Glass Garden Catalog.

tember 27-28 and the Chrysanthemum Show on November 1-2. J. H. Martin of Westbury was elected to active membership and three petitions for active membership were received. President James Gladstone appointed John F. Johnstone, Robert Honeyman and J. H. Andrews to judge the exhibits and their decisions were: 6 ears of sweet corn 1st, James Kelly; a plate of apples, var. "Sops of Wine," exhibited by James Hollaway received the thanks of the society. J. H. Andrews, president of the Oyster Bay Hort. Society, spoke on the coming Dahlia Show in Oyster Bay. Exhibits for September meeting, 6 onions; 3 sticks of celery; 1 musk melon.

ARTHUR COOK, Cor. Sec'y.

WESTCHESTER AND FAIRFIELD HORT. SOCIETY

The regular monthly meeting was held in Greenwich, Conn., Aug. 14, with President Rutherford in the chair. Three new members were elected.

The Flower Show Committee reported final preparations for the show which is to be held in the Greenwich Y. M. C. A., Sept. 12-13-14. Over \$1,200 worth of space has been subscribed for the program booklet. The proceeds from the show will be for the benefit of the Port Chester and Greenwich Hospitals. Schedules may be secured from the secretary, George Hewitt, Belle Haven, Conn. In the exhibits for monthly competition the results were as follows: John McCarroll, 1st, for a vase of Dahlias; M. D. Robertson, 2nd, for a Phoenix Robelenii; James Tough, 3rd, for a vase of Buddleia; Edwin Beckett, 4th, for Thalictrum dipterocarpum; James Linane, 5th, for a vase of Dahlias. For vegetables, James Linane 1st,

Interior of Patented V-Bar Greenhouse Erected on the Estate of Mr. Carll Tucker, Mt. Kisco, N. Y.

V-Bar Greenhouses *Ideal for Growing*

We have been guided, in the scientific construction of the Lutton V-Bar Greenhouses by the experience of the men best qualified to know what is needed, the Gardeners themselves. The light, graceful, rustless V-Bar not only makes the greenhouse beautiful to look at, but adds many years to its life. Note particularly in the above photograph the almost entire absence of shadows. The eave line is unobstructed. Side ventilation is obtained by means of cast-iron wall panels built into the foundations.

Exclusive and peculiar to the Patented Lutton V-Bar Greenhouse is the extra high headroom over the side benches. This is due to the fact that a side light 24" wide x 30" high is used, and either 24" or 30" radius curved eave.

Just as important, however, is our indestructible type of plant benches with galvanized iron frame, porous tile bottoms and slate retaining sides.

No other greenhouse can have the V-Bar construction, as it is patented. The V-Bar itself shows up small when viewed from the side, and the condensation gutter can easily be seen in the photograph.

The man who has a Lutton V-Bar Greenhouse knows that it is the most durable, lightest, strongest, most sanitary and efficient type of greenhouse built.

WM. H. LUTTON COMPANY
260 Kearney Ave., Jersey City, N. J.

John Andrews 2nd, for collections; H. F. Bulpitt 3rd, for a plate of tomatoes, also a vote of thanks for same. Charles H. Totty was the speaker for the evening. His subject, "Roses, Indoors and Out," was one on which he has a wide knowledge. It created considerable discussion, the audience being invited to ask questions. A rising vote of thanks was tendered Mr. Totty.

A report of the Basket Committee was heard. It was agreed by all present that the outing at Silver Lake, White Plains, Aug. 8, was a great success.—ANDREW KNEUKER, Cor. Sec'y.

THE CLEVELAND HORT. SOCIETY

The regular meeting of the above society was held Aug. 9 at the home of C. F. Irish, arborist, with President J. M. Stevens in

the chair. The president requested all members present to stand in silent respect in memory of the late George Jacques, who was superintendent for W. G. Mather, Lake Shore Boulevard, for the past seventeen years, and a member of this society since it was organized.

After the regular routine of business was finished the advisability of holding a Fall show this year as planned was discussed. It was the consensus of opinion that a show on a large scale would possibly conflict with plans for the national show to be held here next Spring, and it was finally arranged to hold a small show among the members only so as to keep up the interest in the growing of exhibition mums, the show to be held some time in November. A vote of thanks was tendered Mr. Irish for his hospitality.

W. J. BRUCE, Sec'y.

COMING EXHIBITIONS

Boston, Mass.—Massachusetts Horticultural Society; Fruit and Vegetable exhibition, Sept. 28 to 30; Autumn and Chrysanthemum exhibition, Nov. 2 to 4. Exhibitions at Horticultural Hall. Sec'y, Edward T. Farrington.

Greenwich, Conn.—The Westchester and Fairfield Horticultural Society, Rye and Riverside Garden Clubs cooperating, will hold an exhibition of flowers, plants, fruits and vegetables in the Y. M. C. A. building at Greenwich, Sept. 12, 13 and 14. Sec'y, George Hewitt, Greenwich, Conn.

Newark, N. J.—First annual exhibition of the Dahlia Society of New Jersey. Robert Treat Hotel, Sept. 13, 14 and 15. Sec'y-Treas., Mrs. Stephen G. Van Hoesen, Fanwood, N. J.

New York City—Annual Dahlia Exhibition of the Horticultural Society of New York, Museum Building, New York Botanical Garden, Bronx Park, Sept. 21 (from 1 to 5 p. m.), 22 and 23 (from 10 a. m. to 5 p. m.) Secretary's office, 598 Madison ave., New York City.

New York City—American Dahlia Society; annual meeting and exhibition, Sept. 26 to 29 at Hotel Pennsylvania. Sec'y, Wm. J. Rathgeber, 198 Norton st., New Haven, Conn.

New York City—American Institute. Flowers, fruits and vegetables, Oct. 3 to 5, at 25 W. 39th st. Sec'y, J. W. Bartlett, 324 W. 23d st., New York City.

CRASSULACEÆ, THEIR PROPAGATION AND CARE

(Continued from page 221)

When the leaf is somewhat withered, it is placed on sandy soil which should be kept moist. A glass plate covers the container of leaf and sand. This keeps the temperature and the moisture as uniform as possible. Roots and small leaves will soon be formed at the notches. The leaf which acts as a store room for the undeveloped shoot will die after a few leaves have been produced.

THE AMERICAN DAHLIA SOCIETY SHOW

By RICHARD VINCENT, JR., PRESIDENT

THE Dahlia of today and the Dahlia of yesterday are two different things, and the Dahlia of the present time will to a big extent possibly change considerably in the near future.

It vies in beauty with any other garden flower, both in formation and combination of color which cannot be surpassed. It is a flower which can be grown by anyone with a little margin of care. It is a flower which attracts either in the palace or the cottage garden.

There is something interesting in the growing of the Dahlia which attracts people, amateur gardeners, and well versed growers. And that is the raising of seedlings; it is interesting to watch their development. It is seldom that a real worthwhile new variety is obtained, although many think they have one when their seedlings come into bloom. When we consider how many varieties named are in existence, we can understand how hard it is to have a variety come which is distinct from those formerly produced.

There are constantly a large quantity of the Peony type being brought forward by raisers, but at the present time what is most needed is types with good stiff stems and of fair size, but not monstrosities, such varieties as can be handled easily and are of good keeping qualities.

The American Dahlia Society is doing good work to help this cause along, and to give growers of new varieties a chance to test out their seedlings of merit. It has two trial grounds established which are looked after by competent men who know and are acquainted with the majority of the older varieties, and can soon after the flowering season inform the raiser whether he has something new or not. The coming season we expect to have trial gardens in different sections started, aiming to carry on the good work to the best advantage of all concerned.

In addition to the Society trial grounds there are several other places where Dahlias can be seen growing and properly labeled. One of these is at the Bronx Park, New York, under the auspices of Dr. Marshall A. Howe (curator of Botanical Gardens). He has over eight hundred plants, comprising over four hundred kinds, old and new

varieties, and it is interesting to note any fine day, when the Dahlias are in full bloom, the number of visitors who are taking notes of the various kinds for their future use.

The Shaw Botanical Gardens at St. Louis, Mo., this year has a goodly collection planted under the auspices of Dr. Moore (director) and we hope to have a trial garden there next year where those varieties most suitable for the Central West can be tested.

The Show of the American Dahlia Society on the Roof Garden of the Pennsylvania Hotel, New York, September 26-29, will undoubtedly be one of the largest the Society has ever held, and any one who misses it will miss a treat.

A large number of Garden clubs who have affiliated, will be with us showing some fine productions. The invitation is open, come, see, and judge for yourselves as to the beauty of the Dahlia.

ON FOREST CONSERVATION

(Continued from page 226)

Now those fires that we have creating such desolation in this state and other states are due largely to one thing, and that is, carelessness on the part of somebody—carelessness! So I appeal to you as gardeners in seeing that the surroundings in which you are located are more beautiful than they are now, that you help foresters wherever they may be in their efforts to keep the backgrounds of the Commonwealth green.

Wordsworth, I think, has said:

"Oh Thou Painter of the fruits and flowers,

We thank Thee for Thy wise design,

Whereas in Nature's gardens our hand may work with Thine.

Give fools their gold and knaves their power,

Let fortune's bubbles rise and fall,

Who sows a seed or trains a flower, or plants a tree is more than all!"

*The Insecticide that
kills plant Lice
of many species*

The Insecticide of Recognized Merit for Greenhouse and Garden

APHINE is a concentrated material—mixes readily in water—efficient in its action—easily applied—free of the disagreeable odors and features of most insecticides—excellent as a wash for decorative plants.

FOR THE GARDEN—As a remedy against all sap sucking insects infesting flowers, fruits and vegetables, APHINE is most effective.

FOR THE GREENHOUSE

—Applied at regular intervals (once each week or ten days) APHINE will keep plants in the greenhouse and conservatory free of insect pests.

FUNGINE—For mildew, rust and other blights affecting flowers, fruits and vegetables.

VERMINE—For worms and insects infesting the soil.

The Walnuts, owned by Mr. D. B. Hayden, Kansas City, Mo.

The Tribute of D. B. Hayden to Davey Tree Surgery

Kansas City, May 1, 1923.

THE DAVEY TREE EXPERT CO., KENT, OHIO,
Gentlemen:

I wish to express to you my entire satisfaction with the work performed by your experts on our trees at "The Walnuts."

I was very much impressed with the very evident ability of your men and the thoroughness and dispatch with which they went about their work.

The improved appearance alone of our trees, as a result of the pruning, in my opinion more than justifies the total cost of the entire operation while I feel sure that the cavity work, of which the attached photograph is a specimen, has added many years to the life of our fine old trees.

Very sincerely yours,

D. B. HAYDEN (Signed)
Gardener.

The operation performed by the Davey Tree Experts on the Walnut at "The Walnuts."

To save fine old trees, every gardener and estate superintendent needs highly skilled assistance. Many, like Mr. Hayden, protect their trees by Davey Tree Surgery—*the science developed by generations of study and experience.* A careful examination of your trees will be made by appointment.

“JERSEY’S BEAUTY”

(Originated by Wm. H. Waite, Supt., for E. D. Adams, Esq.)

*Not only the most beautiful Dahlia, but
more beautiful than any existing flower.*

A TRUE, pure pink, Decorative, of finest form; large thick bloom, of which the outer petals curve back artistically all the way to the stem, lovely soft tints playing through the petals with age.

A color so exquisite, so hard to describe, so perfect and lovely.

The very large beautiful flowers are carried in profusion, gracefully on long, wiry, brownish colored stem, held up straight, facing one squarely.

Great producer; from one plant, enough young stock was propagated last spring, to produce almost two hundred perfect, healthy plants from which more than one thousand perfect EXHIBITION BLOOMS have been cut for flower shows, besides the numerous flowers required for general use on a private estate.

The flowers are of extraordinary keeping qualities both in the garden and cut.

“JERSEY’S BEAUTY” has beaten everything in competition at all the shows where it was exhibited; was awarded numerous GOLD MEDALS, CERTIFICATES, FIRST PRIZES, CUPS, and other high honors.

SCORED HIGHEST OF ANY DAHLIA AT THE TRIAL GARDENS OF THE AMERICAN DAHLIA SOCIETY AT STORRS, CONN., HAVING BEEN OFFICIALLY AWARDED 91 POINTS FOR PERFECTION AND FOR MERIT, GROWN IN COMPANY WITH THE WORLD’S BEST.

Everybody should get this wonderful Dahlia; all responsible firms are going to push the sale of “JERSEY’S BEAUTY” enthusiastically; they want to put it in every worth-while garden in the land.

Plants propagated by Mr. Waite, packed and shipped by him direct to buyers in his Experienced way, guaranteed to grow and produce

Things and Thoughts of the Garden

WILLIAM N. CRAIG

AMONG the most valuable of hardy herbaceous perennials in the flower garden in Fall are the Japanese Anemones. It is true that in some seasons we do not get our full measure of value from them on account of early frosts, so it is always well to give them a fairly sheltered location. While they look well in clumps in a mixed perennial border, they are much more impressive if planted in front of evergreens in large bold masses. There are a number of named varieties all of which are very pretty, but if restricted to but one it would be *A. japonica alba*, the single white form. In my estimation this is incomparably the best either in the garden or for cutting; the semi-double Whirlwind of more recent introduction is handsome but not equal to the older variety. There are several good pink or lavender forms and of these none of the more recent introductions are superior to Queen Charlotte of a pleasing La France shade of color. Fall is not a good time to plant these Anemones, as plants from pots in Spring are the more dependable. While it is perfectly true that they will thrive in full sunshine, they succeed even better when they are in partial shade, and protected from high winds. The ground for Japanese Anemones should be liberally manured and deeply spaded for the best results, which means plants 5 or 6 feet in height. Many amateurs fail to winter these lovely perennials successfully. While with the bulk of hardy perennials it is best to wait until the ground is hard frozen before applying any Winter mulch, in the case of Anemones it is best to give a liberal covering of leaves in order to exclude frost from the roots as much as possible. A common practice is to place a covering of rotten manure on perennial beds just ere Winter sets in. With Anemones, this is better deferred until the mulch is removed in Spring. There are some sections where it is rarely possible to get any flowers before killing frosts arrive, and there the culture of some plants in large pots, which can be plunged during the hot months, or better still in tubs, will ensure a fine display. Grown thus and well watered and fed the Japanese Anemones are splendid for use in the conservatory or on piazzas and porches which are not too exposed. The propagation of Anemones is simple; the thicker roots can be cut in short lengths and placed in a sand bench in a greenhouse, or a little later in the season, a cold frame can be utilized for them. These will produce plants in abundance.

It seems strange that practically no one in America has taken up the hybridization of those beautiful hardy flowers, the Michaelmas Daisies or Autumnal Asters. With the Solidagos they make a truly enchanting display each late Summer and Fall. They are so abundant and common that the average amateur has rather neglected and even despised them, and planted in their stead subjects both less reliable and beautiful. In our native forms there is an infinite range of forms and colorings and many of these are so much improved by cultivation as to be almost unrecognizable. It has remained for a number of hardy plant specialists abroad, particularly in England, to improve the hardy Asters by selection and hybridization, and the bulk of our fine garden varieties have come from there. We cannot all have special borders devoted to their culture such as are to be found at Aldenham Court, Mr. Vicary Gibbs' beautiful and well-kept estate in Hertfordshire, England, whence have come many fine new varieties, but we can at least give them more attention than in the past. Their hardiness is unquestioned and late varieties will show up charmingly when frosts have spoiled such plants as Anemones, Kniphofias, Dahlias, Gladioli, and other Fall blooming subjects. Many are excellent in the wild garden, but spaces should be found for a good number in the perennial border or hardy garden. If wanted purely for cutting, one or two rows may be advantageously placed in the kitchen garden. For those who have hitherto neglected these lovely plants I would suggest buying a few good varieties now, such as Perry's Pink, Dainty, White Queen, Climax, White Climax, Glory of Colwall, Top Sawyer, Feltham Blue, Lil Fardell, Perry's Blue, Perry's White and St. Egwin. I would also suggest buying a packet of a good strain of seed; sowing these in Spring and planting out in rows in the reserve garden will give a surprising range of forms and colorings and some of the very best can be retained for use in the garden borders and others naturalized in the wild garden, if you have one.

* * *

Hardy Asters are rarely seen in pots, yet they make very desirable plants in the Autumn when flowering plants are scarce. For two or three years I grew them in this way and they proved very acceptable for decorative purposes. Seeds were sown in March under glass, seedlings were pricked off and later potted into 3-inch pots, and later to 5-inch ones, the

pots were plunged to their brims in an old hotbed and allowed to root through; treated thus they made nice bushy plants which were smothered with flowers. Some of the hardy Asters are of quite dwarf habit and these are specially good for pot culture. If some grower would like to make a pleasing innovation at a Fall exhibition I should suggest a batch of hardy Asters grown in this way. For those who do not possess a greenhouse, I should say that these hardy perennials can be sown in April or May in a cold frame, planted out when of sufficient size in a nursery row, and all will flower the following Autumn.

* * *

Immediately following the hardy Asters come the pompon Chrysanthemums, in fact a number of varieties of the latter are blooming before many of the Asters have passed. One or two varieties of Chrysanthemums were in good bloom outdoors here in the first week in October, and close flowered varieties of rather small size are found the most dependable. In some seasons the single varieties, which under glass are most beautiful, will do fairly well in this portion of New England but their thin petalage is a decided drawback outdoors when we get windy, stormy weather, for the same reason the large double flowered varieties are not dependable. There is, however, a continued growth in the popularity of the pompons and as late as Thanksgiving they may be seen in many a little garden when all other flowers have passed. At our Fall exhibitions we see collections of what are called "hardy Chrysanthemums"; these, however, are grown under glass and not a few are of no earthly value outdoors. What would be more educational, even though the flowers were of less high grade quality, would be bunches of flowers which had really been grown outdoors. It is for these varieties that thousands of amateurs would cheerfully pay a fair price. While a number of these Chrysanthemums are perfectly hardy in well-drained ground and with me have wintered without protection, if a cold frame is at command, it is good policy to store one or two clumps there over Winter.

* * *

Among low-growing perennials with blue flowers which come in season quite late, *Plumbago Larpentae* is one of the best. The deep blue flowers are carried in clusters, and are produced very abundantly over quite a long period. This plant is a native of the Himalayas and Northern China and in our more northerly states needs some Winter protection. It is a splendid plant for either the rock garden or for a bordering subject and for the blue garden it is absolutely indispensable. The botanists have for some years dropped the name *Plumbago* in favor of *Ceratostigma plumbaginoides* but the earlier name is so much more easily remembered that there is small likelihood of the newer and longer one displacing it.

* * *

It is easily possible to get a fine display of *Delphiniums* late in the season by making one or two sowings of seed of either *D. chinensis* or the *belladonna* and *formosum* hybrids. In late September and through October these make an excellent show, and the spikes produced are on the average much better than old cut back plants. Plants from sowings made early in June are now making a lovely show; the *chinensis* are rather dwarf but on the *formosum* hybrids, spikes a yard in length are not uncommon, and this has been a very arid season with a deficiency of nearly 9 inches in precipitation on October 1. These plants have had no artificial watering but the culti-

vator has been constantly plied about them. Usually in our herbaceous border displays we depend on a secondary crop of spikes from old plants, sometimes they are good but this season they have been somewhat disappointing unless water in abundance has been supplied. The production of this second crop of spikes undoubtedly weakens the plants and makes them more susceptible to disease. Of course, where neatness in the garden is demanded the cutting back to get a late crop is necessary, but if the faded flowers and seeds only were removed there would be a striking difference in the vigor of the plants the following year. With choice varieties it would pay amateurs to try a few plants cut back, and merely remove the seeds from others and note the difference in the vigor of the latter the following season.

* * *

Each year many amateurs fail to successfully winter foxgloves and Canterbury bells. It is not so much the cold as the warmth and heavy Winter covering which is the cause of death. In too many cases, as soon as the leaves fall, they are spread over these and sundry other plants with the idea of keeping the plants warm. This Winter protection should be applied rather with the idea of keeping the ground frozen and preventing alternate freezing and thawing of the ground which causes heaving. A heavy Winter coating of leaves or any other mulch, applied while the ground is still warm, is sure to cause trouble for as the covering gets damp from the Fall rains, it is packed down and not infrequently we have warm spells as late as the middle of November which will heat up these coverings sufficiently to start the rot in the hearts of the protected plants. For this reason it is dangerous to cover them early. An excellent plan is to spread a good handful of coal ashes over the crowns of these plants, which helps to absorb the moisture and acts as a splendid preventive of rot. Where plants are wintered in cold frames and simply covered with dry leaves after the soil is hard frozen and sashes placed over them, there is the same danger of plants damping off, due to insufficient ventilation as Winter is passing. It is also a good plan to lay some fine coal ashes over each crown; the long leaves on the foxgloves should also be cut well back.

* * *

The terrible disaster in Japan is bound to make the supply of certain lilies smaller for the coming season. The bulbs of *L. longiflorum giganteum*, which ordinarily arrive in America in October, will be much delayed and are unlikely to come to hand before the middle of December or even later. However, as Easter is unusually late next year it should still be possible to force these into flower in time. More reliance is likely to be placed on other varieties of lilies during the coming season. *L. candidum* is only grown in moderate numbers; in large pots it is immeasurably the superior of any other white lilies for Easter. It will only stand moderate forcing, however. Quite a number of growers will try out the beautiful *L. regale*. It is easily possible to bring it into flower for a late season. No doubt if placed in cold storage after digging for a few weeks it will force much better. Some of the growers who have been very successful in flowering *Freesias* for Christmas have found that they start to grow much more quickly and evenly if given a few weeks in cold storage and the same should prove true with *Liliums*. The number of *L. formosum* is going to be very much smaller than normal but from Bermuda the stock of

(Continued on page 256)

In the Garden and in the Greenhouse

GEORGE F. STEWART

IN THE GARDEN

WE have again arrived at late October and early November. This season, aside from the practical, which at all seasons has the interest of the plant lover and gardener, attracts the eye of the artist and the inspiration of the poet. Autumn landscapes are familiar in all representative collections of paintings and how often we gardeners have longed for the artist's gift, when in our wanderings round the estate we have come suddenly on some scene which would make a fit subject for a painting. At least we think so, but these gifted mortals of the brush might differ with us. However, they cannot deprive us of our picture, which they probably do not see as we see it. The gift of drawing is of great value to the gardener, and we have known a few excellent gardeners that had no mean gift in that line.

Although I cannot do anything in that direction, neither am I an expert at spelling, I think I can get a glimpse of the viewpoint of that wonderful practical thinker on domestic and world educational affairs, Dr. Eliot of Harvard University, when he expressed himself something like this—that he would rather be one who could paint well than be an expert at spelling.

The poets also have given us word pictures of October. No, I shall not quote Shakespeare, but leave that for Friend Craig. Take this from a New York City poet:

A birdnote sounding here and there
A bloom, where leaves are brown and sober,
Warm noons and nights with frosty air
And loaded wagons say—October.
—Thomas Stevens Collier.

Or again from Massachusetts:

We crown thee with gold, Queen October,
We clothe thee with purple today;
But we leave King November the ermine
To wear with his garments of grey.

Maples, brave knights of thy kingdom,
The oak trees, thy counsellors strong
Are gracefully spreading their mantles
For the queen they waited so long.
—Mrs. Abbie Frances (Fiske) Judd.

Some one may properly ask what has poetry to do with practical gardening? Well, in studying the root meaning of the word poet in some of the ancient languages, I find that the word sometimes used for the production of flowers and fruit comes from the same root; also to use a little sentiment, is not a garden "one lovely song?" I am not a poet—sometimes I wish I could rhyme—but being a plain everyday gardener I shall return to our work.

In the garden, as soon as frost cuts down any of the annual or bedding plants, or disfigures them so that they become unsightly, consign them to the compost heap. The tops of the herbaceous plants are about as good a Winter covering for these borders as we could wish for. Moreover, are they not Nature's covering? If moving, or renovating any of the plants by reducing the size of the clumps is contemplated, the stems may

be laid aside in some convenient corner until the ground freezes enough, so that with this covering the border may remain frozen all Winter. Experience has proved that alternate freezing and thawing is injurious to plants during the Winter. It is far better for the herbaceous borders that they be kept in a continuous frozen condition until Spring. Any work that is going on among these plants should be finished as quickly as possible. Get any replantings of bulbs between the clumps done right away or at least as soon as the bulbs arrive.

Lilies should be planted not less than seven inches deep. We like to dust flowers of sulphur in among the scales of the bulbs before covering the bulbs with peat for about two inches deep, having the same under them, and then covering with the ordinary border loam.

Tulips and Narcissi should be planted about six inches deep, that depth is also correct for Hyacinths. If the bulbs are of first quality and free from disease, they should last in the borders without being disturbed for at least three years. We have had them do well for five years without being lifted, but after three years it is generally best to lift them and only to replant with the best bulbs.

Small clumps of Grape Hyacinths, Crocuses, Scillas and Snowdrops may be planted three to five inches deep near the edge of the borders. They are the first or among the first flowers to greet us in Spring, and who has not been thrilled when the first flower is found open?

Fine Fall displays may be enjoyed with the early flowering Chrysanthemums, if one has the time and material to afford them protection at night. Unfortunately, as I pointed out in last month's notes, inland from the seashore, many of us are located in early and late frost belts, which do not prove favorable to these beautiful Fall flowering plants, especially if, as last year, they were accompanied by a blasting wind.

In the formal garden, as soon as the Summer bedding plants have been cleared away, the beds may be dug over and planted with bulbs. In my opinion these formal bulb gardens are too often overcrowded. The blaze of color becomes tiresome. I think it would be far better to have a groundwork of pansies or forget-me-nots and two sets of bulbs of the same color, if at all possible. Early flowering Tulips and late Darwins or Breeders could be planted in the same bed, alternate rows of each, or perhaps better still, an early flowering bulb and a late Darwin bulb. One set would be out of flower about the time the other would come in, extending the season considerably when these deservedly popular flowers may be enjoyed.

There is no doubt in my mind, that the ideal place for growing and enjoying all the Spring flowering bulbs is on the edge of woodlands, where the grass grows naturally and perchance some brook meanders its way through the plantation. Some of us have seen and enjoyed many such places "in the happy days gone by" and we are still full of hope that we shall yet see many of these beautiful natural Spring scenes.

All the Gladiolus bulbs, except perhaps the last planting, may be lifted and dried in the sun. A sunny slope is the best place to dry them, and in case of rain a few shutters placed over them will help the ripening process. We always put in a plantation of these bulbs

about July 15. We make this the largest planting of the season, the reason being that during the frosty nights which occur during the Fall, many of the tips of the flower spikes are injured. After a frost we very often have a spell of fine weather, and the plants continue flowering. The few that are nipped are not missed very much. We do not lift this late planting until the stems are ruined by frost, neither do we dig up the small bulblets that we sowed in a drill in the Spring until the tops are cut down. As a result we very often have cut fairly good Gladioli in November from both of these plantings. With protection they could stay out all Winter without injury.

Dahlias, as soon as they are blackened by frost, may be cut down and dried. Tie the labels to the bulbs with copper wire for there is less danger of losing them. They winter well in a frost-proof cellar.

Cannas need a little warmer place to winter in and a somewhat drier atmosphere. In fact, some of the finest and freest flowering Cannas we have grown need to be kept growing all Winter to make sure of a good stock in the Spring. We have had this experience with some of the finest French varieties.

Any one who is contemplating making a new rose plantation next Spring, ought to have the ground prepared now. While roses will grow well in almost any good garden loam, yet if the best results are desired they should be as well treated as any bench of roses indoors. This necessitates good drainage, the best of good sod loam, preferably inclining to clay, and a good mixture of the usual rose manures. The rose plants should be secured now. They can be kept by covering them over with loam outdoors and will be right at hand in Spring. These plants will be in a far better condition to plant than much of the stock one is likely to buy in Spring. I know that Fall planting of roses is advocated by many good growers, but that question, like many others, is debatable.

Montbretias need protection during the Winter. Though they can be lifted and stored in a cellar where atmospheric conditions are about right, yet the best place for them is in the soil. Cover them well with leaves and if drainage is good they will winter alright. They may be grown in the same ground two or three years without lifting.

Secure a few roots of the choicer herbaceous plants or any that stock is short of. During Winter they may be propagated if kept in a growing condition.

There will be a great deal of work keeping leaves cleaned up about this time. We find that for potting purposes oak and beech leaves are the best and we try to keep them separate from the others as far as possible. Keep the grass mowed until a good stiff frost stops it from growing, which makes it easier to rake the leaves off the lawn, and in my experience it does the grass no harm, although others think otherwise and allow it to grow quite long.

There is still plenty of work in the vegetable garden. Some crops are yet to be harvested, which should be done now as quickly as possible. The ground should be dug or ploughed before severe frost sets in. Any weeds that have not been taken care of are covered up and will be decayed before next Spring. Trenching of land is now almost prohibitive on account of the cost and scarcity of labor. Late vegetable rubbish may be decomposed in a heap under cover if possible, adding some acid phosphate. It will be easier ploughed under in the Spring. Anything in the way of decayed vegetable matter is now worth saving as organic manures are becoming more scarce every year.

Cauliflower, with us, has been of far better quality this year than for several years past. During the war,

seed selection evidently received very little attention, resulting in heads of poor quality. If not all used up before severe frost, they may be heeled in in a deep frame. Water the roots well, but keep the tops dry by airing them well during the day; very little loss will result until they are used up.

Late lettuce and endive does not pay to be lifted from outdoors, a covering of straw or salt hay will take care of them until they are used up. Heads that have developed late in a cold frame if properly aired will last well through the Winter.

Have a good supply of beets, chicory and Ruta Baga turnips stored in a cool cellar. All these, when forced in a mushroom house temperature make excellent salads during the Winter.

Do not neglect the asparagus plantation after the tops are cut. If it is on a fairly level piece of ground give it a heavy manuring and dig it in, for it will not leach out. But if it is on a slope, it is better to wait until Spring. Burn the tops, as borers are likely to be in them.

Rhubarb and seakale may be lifted and stored before the ground gets too hard, that is, if forcing of such plants is practiced. But always remember that the size of the family to be supplied has to be considered, together with time and facilities.

IN THE GREENHOUSE

In the greenhouse the chief attraction for some time will be the Chrysanthemums, but do not become so enthusiastic over them as to neglect other things. A great many details attended to now will determine how steady a supply of plants and flowers the greenhouse will produce during the Winter. The tendency these days is to specialize, which may be alright for a florist, but never for a private gardener. The better acquainted a gardener is with a great variety of plants and their cultural requirements, the chances are that he will give more pleasure to the owner. People get just as tired looking at a few genera of plants as they do with food, if it is not supplied in variety.

The worst pest, after Chrysanthemums are opening their flowers, is red spider, especially if the greenhouses are near trees that are affected. On a hot day, with quite a breeze blowing and ventilators all open, in they come. Very little can be done with a case of this kind, as syringing will be sure to hurt the petals. Keep them thoroughly clean until they show color. Look out for the ventilator on the windy side and keep it closed. Do all watering in the early part of the day as an excess of moisture is also bad for opening flowers. Withhold food as soon as the petals begin to unfold, as by this time there will be sufficient in the pots to carry them through to completion. Take note of all undesirable varieties while they are in flower. Attend the exhibitions and form your own opinions about the newer ones as far as one can determine by observation.

Have a good stock in small pots of the usual annuals that are used for forcing. There are quite a number of good things as yet untried to any extent here for Winter forcing, which do well in a temperature around 50 degrees in our clear Winter sunshine. The heat outdoors in Summer is too much for them, but they thrive well in the Chrysanthemum house, giving variety for cut flowers, aside from the usual standbys such as carnations and roses.

Cool hardwood plants from now on need to be more carefully watered, and if possible, rain water should be used for them. I have urged the use of rain water before in greenhouse watering, as its use cannot be emphasized too strongly. Anyone who has not used

it would be astonished how it simplifies the culture of plants indoors.

The larger and more vigorous growing cyclamen plants may yet receive another shift. They may be brought along slowly in a cool house, keeping them away from draughts. They will be very serviceable in March and may prove an attraction at some exhibition in that month. Fumigation of these plants must never be neglected, and if the usual precautions are observed, hydro-cyanic acid gas is the most effective. Again I would draw attention to the valuable little booklet which the Roessler & Hasslacher Chemical Co. will supply free from their office, 100 William St., New York City. It gives the simplest and easiest advice to follow about how to use this gas in greenhouses that I have so far seen. They have specially prepared sodium cyanide in egg shape, weighing one ounce, which is most convenient to use. I consider they have done the greenhouse men a great service by getting it up in this convenient form. It is now time to begin using hydro-cyanic gas in light doses on all plants that are not injured by it. It is the best thing so far we have found for mealy bug, scale and white fly. If done regularly and with care it keeps these insects in check. We never use it in the hot months of June, July and August, and generally by this time of the year these insect pests put in their appearance.

Carnations that were benched in the end of June will now be throwing up good flower stems. The bench will be well filled with roots and an application of plant food will help them. They respond to Clay's fertilizer, decayed horse droppings and light applications of tankage.

Fuchsias that were rooted about the first of August ought to be in five-inch pots early in November, that is, if large plants are desired by the end of May next year. They may be trained in different ways but we prefer the pyramid form.

Any plants that are to be grown into large specimens should receive a shift before they get too well rooted. As soon as the roots put in appearance all around the ball, it is time to shift them. This is especially true of cool soft wooded plants such as herbaceous Calceolarias and the so-called shrubby type.

Well matured leaves of Begonias may now be placed in the propagating bed. We have had the best success by potting them in small pots in sphagnum moss, sifted fine. It is better not to insert the leaf stem too deeply in the pot. To steady it, use a thin peg about the thickness of a toothpick and a little longer. Pushed through the leaf and firmed in the small pot, it will keep it from tipping over. About 80 degrees bottom heat should be maintained until roots are formed. All Begonias will root from leaves and generally will make better plants than those rooted from cuttings.

The Fall flowering Cattleyas will now be in bloom. We like to keep the varieties, Bowringiana and labiata, close to 60 degrees at night until they finish flowering. Cattleya labiata is susceptible to losing its leaves after cutting the flower, if it is not given a clean cut and the cut made in such a manner that moisture does not lie at the apex of the leaf. Keep the plants quite dry for a little while after cutting the flowers.

By this time the late grapes will be ripe and plenty of air and a dry atmosphere must be maintained to keep the fruit. We believe that a better flavor is maintained in the berries by leaving the bunches on vines than preserving them in bottles in a fruit room. If kept cool and airy they will generally keep as long as desirable. Keep up fumigating with hydrocyanic

gas from now until they show signs of starting in the Spring. We do it on the vines every two weeks and any mealy bug that may have come in from outside will be killed before they start growing next season. Store the pot strawberry plants after they have been frozen a little in a cold frame, from which they can be forced in batches after the turn of the year.

GLORY OF THE SNOW (CHIONODOXAS)

THE several varieties of Chionodoxas or, as they are popularly known, Glory of the Snow, are, when taken together, a small group of charming early Spring blooming bulbs, blooming with the earliest warm days of Spring and producing their showy and attractive blue flowers in the greatest profusion in dense clusters, on stems that arise from clusters or clumps of grass-like foliage to a height of five or six inches, writes Charles E. Parnell in the *Flower Grower*. All are natives of Asia Minor, so are perfectly hardy in the vicinity of New York, with a slight covering of some sparse littery material during the Winter months, or from December to March. They can be used to good advantage when grown in groups, in the rockery, or front rows of mixed flower beds or borders, where they will be found to be very attractive during the late days of March or early days of April; the precise time depending entirely upon the season and situation in which the plants are grown.

The bulbs do best when planted during the month of October in a well-drained, deep, moderately enriched soil; placing them in groups of about a dozen bulbs, keeping the bulbs about two inches apart, and covering them to the depth of about two inches. They will require but little attention after being planted until the bulbs commence to crowd each other, when it will be necessary to replant.

Of the several varieties *C. gigantea* is the most robust as it attains a height of about nine inches, and the large lilac-blue flowers have a pure white center and are borne in very dense clusters. *C. Luciliæ* has deep blue flowers, each petal being veined with white. The flowers of *C. Sardensis* are of a deep blue throughout.

The late J. L. Childs in "Popular Bulbs and Their Culture," in speaking of the Chionodoxa says:

"Its name means Glory of the Snow, and is derived from the fact that the bulbs bloom among snow and ice very early in the Spring. It is a native of Asia Minor and resembles a Scilla to some extent though much more beautiful. The flowers are borne on graceful spikes and are about an inch across, intense blue shading to white in the center. For a mass in the garden, for early Spring flowering, nothing can be more lovely, and as it is perfectly hardy in any location it should be extensively planted. For Winter blooming in pots it is magnificent, but will not stand forcing in heat. It must be grown slowly in a cool atmosphere to bring it to perfection. None will miss it by planting this little gem extensively both for pot and garden culture."

Progress in the sense of acquisition is something; but progress in the sense of being is a great deal more. To grow higher, deeper, wider, as the years go on; to conquer difficulties, and acquire more and more power; to feel all one's faculties unfolding, and truth descending into the soul,—this makes life worth living.—*J. F. Clarke.*

Lilies for Every Garden

HELEN M. FOX

THE lily is always conspicuous and lends a stately beauty to any scene it graces. What other flower shows as much variety of form, foliage and color? Can the loveliness of the jewel-like flowers of our native *superbum* be surpassed, with their perianths of red, green and orange swinging like gayly colored bells from their tall stalks; or the open spreading, white *auratum*s, with a pale, golden band marking the center of each segment, their stems swaying and bending under the weight of the heavy flowers,

Lilium auratum

so fragrant that the perfume spreads over the garden, and through the windows into the house at night; or the *humboldtii*, a Californian, like orange birds with spotted breasts, their perianth segments rolled back to the stem, their pistils and stamens curving outwards, making them appear in flight across a green meadow; or again the *philadelphicum*, like a ruby colored grail holding its cup to the skies. The color combinations in any one flower can serve as a model for artists, where emerald green, rosy pink and white are used as in *speciosums*, or greenish brown, gold, purple and white as in *regales*. Nature, the master artist, is at her best here and the color harmonies are worked out to the minutest detail, even to the varying shades of the pollen. From gradations of brown, orange, gold, black, purple and red, the one is chosen which tones in best with the other colors.

All this beauty can be yours, as lilies are easy to grow. Most people have the fallacious impression that they are delicate and finicky because, in the past, we Americans have taken our garden lore principally from the English. When they found their damp, sunless climate unsuited to them, we thought the same must apply to us. Most lilies like hot Summers with plenty of sunshine and a dry period to rest in after blooming. In general it is best for the people living on the West coast of the United States to grow the European kinds and for those on the East coast to grow the Chinese and Japanese, and for all to cultivate whatever species is indigenous to their region.

With so many beautiful native lilies, how foolish it is not to make full use of this convenient material ready for us to paint our gardens with. *Canadense* and *philadelphicum* lilies grow wild in the meadows of my own farm and transplanted to the garden they grow taller and stronger and are the June sensation, with their yellow and orange perianths with white *candidums*, blue *delphiniums* and purple Japanese *irises*.

The longer one gardens the more one realizes that certain plants do wonderfully well on the hill, while they are a failure in the valley. Sometimes on one side of a stream a plant will flourish that will languish on the other bank. To have success with lilies try out many kinds and then specialize with the ones that thrive on your place.

Fine lilies come only from good stock. Beware of the cold storage bulb. Buy medium sized bulbs in

Lilium regale

preference to the largest which are forced to increase their bulk, weight and price, but lose in vigor and are more subject to disease. The shorter the time they are out of the ground the better, as they must not dry out. If possible buy from the grower. Sometimes this cannot be done, as he may not have the rare varieties. If they come from a distance and arrive after the ground is frozen, plant the bulbs in boxes and winter in the cold frame. When the shoots come up in the Spring, transplant to their permanent place. Before planting examine the bulb carefully to see if there are any slimy scales. These are caused by a disease called *Rhizopus necans*. Bulbs badly affected with this have an unpleasant odor. Dust the bulbs with flowers of sulphur before planting to prevent this. There is another lily disease called *Botrytis cinerea* which shows itself by yellow spots on the leaves. Plants having either of these diseases should be destroyed.

Once the bulb has arrived and is healthy, the best

way to plant it is to dig a hole three inches deeper than needed and fill in to the required depth with sand; then place the bulb sideways on this and cover to the top with more sand. A layer of sphagnum moss under the bulb is good. The principal thing is to have good drainage and to see that no manure touches the bulbs. The lilies that root only from the bulb do not need to be planted as deeply as those that root from the stem too. The deepest planting should be about eight inches from the top of the bulb to the surface as for *tigrinum*, *canadense*, or *henryi*, while the top of *candidum* should be only one inch below the surface. Never plant closer than a foot apart; spacing depends on the size of the bulb. After the plants are established it is well not to move them.

Lilium canadense

Some of them will form clumps in time and can then be divided. The question whether lilies can stand lime in the soil or not has been much discussed. Many lime-hating varieties thrive in my perennial border where the presumably insidious material is spread quite thickly every Spring. I have, however, no bog lilies. To winter out of doors they are mulched like any other perennials with leaves or straw held down by pine boughs or corn stalks.

Lilies can be propagated by division, offsets, bulbils and seeds. Little has been done in hybridizing them, and here are untried fields for the pioneer. The shape of the flower lends itself easily to crossing. When the pistil is receptive, it is covered with a sticky substance. The seed pod turns upwards after the perianth has fallen off when the pollination has been successful. Most lilies have to be hand pollinated; I have gathered seeds from *tenuifolium*, *candidum*, *regale*, *canadense* and *superbum*. The seeds are planted in boxes with one-third sand and two-thirds leaf mould and put in a cold frame in partial shade and kept moist. In Winter they are protected with a mulch of leaves, and the second Spring they are transplanted. Some will bloom the second Summer and all the third after planting. It seems a long time to wait, but gardening requires patience. Nature deserves our gratitude for making her own pace, and

no nervous effort of man can change her majestic, tempered intervals.

The lily procession in my garden is led by *elegans* the second week in June, with *henryi* bringing up the rear as late as September 15. There are usually three kinds in bloom at one time and the end of June and beginning of July there have been as many as eight varieties flowering simultaneously.

All of the following list do well in the middle Atlantic States:

L. auratum (golden banded lily of Japan) needs renewing every few years if planted in rich soils; white spotted red with gold bands, fragrant, semi-shade, stem rooting late July, August.

L. brownii (Brown's lily), cream, brown outside, fragrant, early July, bulb roots.

L. candidum (Madonna), white, fragrant, bulb roots, late June, July. Needs renewing with me.

L. canadense (Meadow Lily), yellow, rhizomatous roots and stem roots, late June, July.

L. croceum (Orange Lily), bright orange, stem rooting, late June, July.

L. elegans (Thunberg's Lily), orange red, stem rooting, June.

L. hansonii (Golden Turk's Cap Lily), bright yellow semi-shade, stem roots, late June.

L. henryi (Henry's Lily), orange, stem roots, August.

L. humboldtii (Humboldt's Lily), orange, semi-rhizomatous, July.

L. grayi (Asa Gray's Lily), red and yellow spotted brown, rhizomatous, late June, July.

L. martagon (Martagon Lily), var. *album*, white, small flowers, stem rooting.

L. philadelphicum (Wood Lily), some stem roots, red, June, July, bulb rooting.

L. regale (Regal Lily), fragrant, white golden throat, stem roots, July to early August.

L. speciosum (Lance-leaved Lily), fragrant, rosy or white with green heart, rhizomatous roots, late August, September. Do not plant too deep.

L. superbum (American Turk's Cap Lily), red and orange, very tall, late July, August, some stem roots, rhizomatous.

L. testaceum (Nankeen Lily), pale creamy buff, late June, July, bulb like *candidum*.

L. tigrinum (Tiger Lily), stem roots, August, September, pinkish orange.

L. tenuifolium (Siberian Coral Lily), dwarf orange, needs renewing every few years, no stem roots, June, early July.

When only a few lilies can be grown, I would suggest: *regale*, *canadense*, *superbum*, *henryi*, *speciosum*, *tigrinum*. A secondary list has *croceum*, *tenuifolium*, *auratum*, *candidum*, *humboldtii*. One cannot make a mistake by choosing any of these for appearance and reliability.

If one has the requisite space to indulge one's fancies to the fullest, lilies are at their best planted amongst low growing evergreens with higher evergreens behind them. Some shade-loving kinds are good planted at the edge of a woodland. In the border they should be placed against the wall of the house or garden, in some wind-sheltered locality, so that they do not have to be staked. They look well under pergolas, on the sides of steps or in any part one wishes to emphasize. In the border there are many effective ways of using them. The early low-growing *tenuifolium* and *elegans* planted with blue *Campanula persicifolia* make a pleasing picture. The *tigrinum*s are used so much that we tire of them, like

Notes From an Old Country Garden

ARTHUR T. JOHNSON, F. R. H. S.

DURING the last few years we, in this country, have been paying closer attention than we used to do to those berry-bearing shrubs which give such a fine Autumnal and Winter display of brilliant colors, and among them few have become so popular as the barberries. The genus *Berberis* is, however, such an enormous one and cultivated kinds are so numerous—to say nothing of the confusion that still exists over their nomenclature—that one can not do more here than mention a few of the most noteworthy.

A first favorite with us is *B. Wilsonæ*, which was brought from W. China in 1904 by E. H. Wilson. It is an exceedingly elegant little shrub of some three feet in height, and its pretty yellow flowers are followed in the Fall by an abundant crop of large fruits of a clear, almost translucent, coral-red, tinted with salmon. The foliage at the same time assumes gay tints so that the little bush becomes a most striking feature of the Autumnal garden or woodland. With berries of much the same color is *B. Pratti*, a considerably taller shrub, and another excellent one of the same class is *B. corvii*.

Our native barberry, *B. vulgaris*, which, I believe, is naturalized in parts of North America, is a species of no little merit as an early berrying shrub, and the clusters of brilliant scarlet fruits, which are seldom eaten by birds owing to their acidity, will often remain on the branches from September to March. The variety *purpurea*, with plum-colored leaves, is a decided acquisition to the species. Another early barberry, and one that is as much appreciated in some of the Eastern States as it is here for its hardiness and brilliant tints and berries at this season, is *B. thunbergi*. This is one of the old and well-tried members of the genus, and another excellent species is *B. aristata* which grows a good deal taller and whose grape-like bunches of berries are a dull red covered with a bluish-white bloom.

Like the barberries, most of the cotoneasters hail from China or the Himalayas and the majority of them are perfectly hardy here. From the lowliest creeping species to those which attain the stature of a tree, this genus affords several species which are surprisingly beautiful when adorned with their crop of Autumnal fruit. One of the handsomest is still, I think, the old *C. horizontalis*, especially when it is allowed to grow naturally in bush form rather than attached to a wall; and its variety *perpusilla*, whose fishbone branches are held on an horizontal plane instead of tilted, is equally good. One of these splendid shrubs, laden with its burden of large round berries, which glow with rich shades of orange to deepest crimson, is a most arresting sight and one that is rendered still more gorgeous by the bronze and wine-colored hues of the foliage which precede the leaf-fall.

Another first-rate cotoneaster is *C. bullata* (*moupinensis*) which produces ample bunches of crimson fruits as large as small cherries. Nor can one overlook the merits of *C. houpehensis* which, unlike the rest of its tribe, can make some claim for beauty as a flowering as well as a berrying shrub. *C. pannosa* is a species of marked distinction, the only member of the genus, which is something like it being *C. Francheti*. But the former, a bush of some eight to ten feet in height, is much the more graceful, its long, whippy

branches clothed with their silky, evergreen leaves being surpassingly elegant. The crimson berries of *C. pannosa* do not ripen here until November, but they remain long on the branches and, though individually small, they are borne in such bountiful clusters that a well-laden specimen is a most gorgeous spectacle. Other good and well-tried species are the familiar *C. simondsii*, *C. applanata* (*dielsiana*) and the tall, tree-like *C. frigida* with large bunches of fruits like those of our mountain ash (*Pyrus aucuparia*). Of the creeping cotoneasters which are most reliable in fruiting freely with us, and which are of such inestimable value in the rock-garden, are *C. adpressa*, a deciduous species, and the evergreens *C. congesta*, *microphylla* and the entirely prostrate *C. humifusa* (*Dammeri* var. *radicans*).

There are not many gardens of any size over here where some representatives of the Sumachs (*Rhus*) are not grown for the beauty of their foliage in the Fall. The commonest is perhaps the Venetian Sumach (*Rhus cotinus*) of which there is an attractive variety which is purple in leaf, young wood and flower. But a choicer plant, to my mind, than *R. cotinus* is *R. copallina*, well-known to all tree-lovers of its native home, the Eastern United States. Here this pretty shrub does not grow more than about four feet high, but its leaves color well before they fall and the bright-red fruits of the female tree are highly decorative. Another most desirable dwarf American Sumach which we value very highly, both for the elegance of its Summer foliage and the fine tints which it assumes at this season, is the variety *laciniata* of *R. glabra*. The long, broad, "feathered" leaves of this sumach produced on well-grown specimens cut hard back in Spring are remarkably handsome.

Very charming beneath the tall oaks of our woodland garden and about the lawns and rock-garden are the colchicums, or Autumn crocuses, of which *C. speciosum* is still one of the best. But grown in bulk with a carpeting of natural herbage the old *C. autumnale* in various shades of rosy-lilac is very effective. Of both of these there is a pure white form which is very lovely. Contemporary with these are those hardy cyclamens, such as *C. neapolitanum*, the Ivy-leaved Cyclamen, and *C. Europæum* which will usually be in flower from September, or earlier, to the end of October. The former blooms before the leaves and its dainty, rose-pink blossoms, rising in little colonies among the ferns and grass of our woodland floor, are perhaps the most fascinating of all autumnal flowers. Then when they have died down and are busy converting their seed stems into those curious spiral springs which so cunningly ensure the dissemination of the seed, the foliage appears. And this leafage, so attractive in design and so beautifully mottled and margined with a silvery sheen, will be one of the most delightful objects of the garden throughout the wintry months.

One of the gayest masses of color in the borders just now, if we except the asters, is that of some large groups of *Sedum* spectabile. This noble old stonewort is not perhaps what one would call a good color—not even in the forms with flowers of a richer tint than the type. But its foaming heads of blossom, which are just the color of a raspberry-ice, are wel-

(Continued on page 254)

Fireside Gardening

HENRY J. ECKSTEIN

MY title may impress the practical gardener as paradoxical, if not indeed entirely ridiculous.

And yet, in any activity there must exist, underneath the reality, the realm of imaginative thought. Although gardening may appear to be confined to simple actuality, this is none the less true. When the gardener has laid aside his tools, crops and seeds, he must perforce take time for the planning of the approaching season's work, and at that time the opportunity, in fact the need, for the employment of imagination and vision presents itself.

Somewhere along in February or March, preferably as early as January, the gardener naturally turns toward the preparation for the coming garden year. When Nature commences to display its new life, with the swelling of buds and the rising of the sap, he also feels a new life rising in him, increasing as Spring approaches. In April he is at full blast; as interest grows, new hopes, new ideas, and greater efforts crowd on him, as if he did not know of the discouragements and obstacles lying in wait—blights, diseases, droughts and accidents. Flushed with the success of the first blooms, he rushes on madly, flaunting his joys and garden beauties, tilting away quite untouched by coming adversities. When these are first encountered in mid-Summer, he struggles bravely to defy them. But toward the end, when the last plantings have been made and nothing remains to be done but cultivation, his enthusiasm is likely to wane. I often think that August brings the gardener's severest trials. Not only does the dry heat naturally make energetic effort difficult for the gardener, but it sorely tries the garden itself as well. Routine work and discouragements that are often overwhelming affect his interest and endurance.

This thought is very quaintly expressed by Maund in his *Botanic Garden*. "Mid-Summer, or the Summer solstice, presents itself to the contemplative man as that point of time which, like the prime of life, may be called the pivot of our expectations, on which anxieties change their balance. With what desires, hopes and anticipations each vernal ray inspires the zealous botanist, just as buoyant spirits excite the youthful mind. Pleasurable prospects still continue to arise till that fated day—the longest of the year, to which we have just alluded, like the strongest of man's life—when no longer does each succeeding day outstretch its predecessor in length or strength, but a shadowy reverse commences, when the season of brilliancy has risen to its zenith, or man to the perfection of his nature, then, and not till then, arrives a full reflection on declining days. If, however, the cultivator of a flower garden, or the years of human life, has indulged due thought of a future season, if his young plants be well trained, his whole garden in good culture, and he has made preparation to meet the icy hand of a Winter fast approaching, all is well; he fears not present nor future storms, all seasons alike afford him pleasure."

But the true gardener goes through to the end, eager to commence anew, engrossed in new ideas. He reaches this phase in the early Autumn, facing the long Winter without any opportunity for actual endeavor, other than the making of plans.

This appears to me as the seasonal adaptation of the gardener to his work and the laws of his material.

It is the psychological explanation of what I like to call "Fireside Gardening."

But it does not by any means comprehend all of it. At the fireside we can build our dream gardens where everything grows easily and profusely, free from all adversity or misadventure. Surrounded by books and catalogs, working among memories and fond visions, the gardener builds a garden which in every way expresses and fulfills his ideals. There are no weeds, no pests, no failures, just succession after succession of perfect flowers, unfolding each in their precise turn, taking with the utmost regularity and dependability their place in the harmonious scheme of his picture garden. As he sits by the fire and sees lovely white lilies, gracefully opening against gigantic staffs of delphinium, the mice are not unlikely feeding on the bulbs under the snow, but he knows it not. Or the frost is killing the roots of some other tender treasure, while he is so confidently counting on these same plants as vital to his next year's achievement.

He reads in the books of the greatest of all gardeners, the English, of this or that fine thing which he has never grown, and it seems the easiest thing in the world to grow. Indeed it is rather a poor gardener who does not straightaway drop the books and order seed or plant. Is there anything more delightful or simple than to follow the precepts of Mrs. Jekyll, as she so facilely describes those perfect, harmonious gardens of hers, where, month by month, new vistas unfold in the subtlest of color schemes, magnificently blended in the greatest of profusion?

Or as he pores over catalogs his list lengthens beyond his capacity, as he is enticed by the occasionally misleading descriptions. The results of all experience are forgotten and cast to the winds as he capitulates before the allurements of seedsmen, who are ever ready with their "of easiest culture," "no garden is complete without this rare gem," "altogether a charming variety," "easily raised and blooming continuously," and what not. One is often tempted to think that seedsmen must have a dictionary exclusively their own where "continuous" and "easy" have different meanings than the common ones, or else meanings obsolete to all but seedsmen and most assuredly foreign to the practical gardener. Or are the seedsmen only more imaginative and visionary than the gardener?

With equal facility and joy the Alpine enthusiast follows Reginald Farrer into Japan or Thibet, or over the sterner Rockies. Or else he passes "A Collecting Day Above Arolla" with him and is amazed at the ease with which he brings the treasures there culled into his own gardens. Mr. Farrer is the most human, the most graceful and poetic of all writers on gardens, in my mind. He has so delightful a sense of humor, so engaging a personality, that in reading him it becomes no difficulty whatsoever to grow almost two hundred *Saxifraga*, or to find the right soil and place for such elusive plants as *Androsace*, *Gentiana* or *Ramodia*. The frailest, the most sensitive and "miffiest" of Alpines seem to bloom for Mr. Farrer in his garden, and his descriptions of them are so fascinating, his modesty makes his success so much a matter of fact, that we cannot read him without immediately growing these same things ourselves.

Yes! growing them—in our fireside gardens. And

if you say: "Ah! but not elsewhere!" I must ask: "Is it absolutely essential that we actually do grow them elsewhere?" I do not contend that we can long be satisfied by merely picturing these things in our gardens, but I do feel that the spirit of the real gardener should admit occasionally reading of these things, and playing with them in his mind, and not actually growing them. By all means let him try. But is it so serious if he fail? There is pleasure in the defeated attempt, especially if one is gardener enough to try again.

I have tried hundreds of things under adverse conditions, and failed many times. But that does not daunt me. For such efforts are the essence of the art. The gardener often gets a greater thrill from a single success with a rare or difficult plant, which may only have produced a single bloom, than from all the rest of the garden. This appears to be the true spirit of gardening. And if we go on simply planting phlox, verbena, pansies, etc., no matter how fine individually they may be, are we not missing a great deal of the real joy that the garden offers? We need not forego our successes "en masse" to have these single triumphs, but it often seems it would be worth while to do so, if it were necessary.

Such efforts, repeated again and again if need be, despite mishaps or errors, are but too few among our American gardeners. We are all apt to confine ourselves to the easiest and most commonplace in our desire to succeed and create display. I grant that in our gardens and exhibitions we must have bloom, in quantity and quality, but must our trial beds and nurseries be so completely ignored? The creation of a novelty that is worth while is, and should be, the height of achievement in gardening. It is a rare art and a difficult thing to do. But we should find some place to record at least efforts that do not so signally succeed.

It is of great value to keep on trying the new, the difficult, even the apparently impossible. But it is discouraging so to do, if we have no opportunities to exchange and bring to notice the disappointments as well as the achievements, whether these be in the direction of the creation of new varieties, or the attempt to grow varieties not previously established in our native gardens.

We need more "Fireside Gardens" if we would improve our outdoor gardens, in diversity or form. It is comparatively easy to build a garden, rich and full, colorful and luxuriant, if we use the tried materials that we know will be effective. But we are not really gardening, in the finer sense.

We have only to compare any American gardening book with an English to see how limited is our scope. If we exclude two or three, we find every nursery and seed house in the Eastern part of the United States offer the same species and varieties, within a variation of about 10 per cent. If we compare these with foreign catalogs, we realize what novices we, after all, really are. Here and there one finds a large estate, superintended by an unusually experienced man, who may specialize more extensively in one thing or another. But to the general run of gardeners, professional or amateur, there are ten things that are a sealed book to one that is known.

The usual reply to this thought is that the things known are those that have been tried and found adaptable to our soils and climate. But there are things not known that should be tried, and with which we have a fair chance of success, and if we have an equal chance of failure need we be deterred?

If we pick up any garden paper we find its columns filled with accounts of successes. The only records of failure are those of readers who, in a hesitant, despondent way, write to the editor for advice, or else they will fling their failure forth, in a tone of abandonment, as if to say: "So there! You see it cannot be done." We need these thwarted efforts and should encourage them. They are the very life of progressive gardening, the hope of future development, the product of research and imagination, the labor of adventurous spirits. The desire to make these attempts does not so much arise in the Summer when we are busily tending our growing gardens, nor in the Spring when we are equally occupied in preparing for that season. They are the outcome of long hours spent indoors, when we have the time to sit by our hearths and study our books and dream of our next year's gardens. The seed of the growth of American gardening should be planted by the fireside.

NOTES FROM AN OLD COUNTRY GARDEN

(Continued from page 252)

came by all the butterflies in the neighborhood, and for that alone they are worth growing. Another late sedum which is less commonly seen and very much more attractive is *S. pulchellum*. This hails from the States of Missouri, Virginia, and others, and it is not only one of the most beautiful of hardy sedums in cultivation in this country but it is in one respect unique among its kind, that is, it prefers a damp and cool rather than a dry soil. *S. pulchellum* grows here with the greatest ease (provided its peculiar taste for dampness is recognized) and its large, claw-like heads of rosy-carmine flowers which crown the sea-green, leafy stems may be counted upon to afford a bright display throughout the Fall.

Though we have comparatively few American sedums in cultivation, one or two among them might be singled out as of outstanding merit. The above-mentioned is one, *S. spathulifolium* (Hooker) is another, and if I may add a third I should mention the blood-red, golden-flowered *S. oreganum* (Gray). It would be difficult to name a trio of higher merit for out-door culture here than these, and some of the newer forms of *S. spathulifolium*, whose large, fleshy, plum-colored rosettes are powdered over with a silvery-grey meal, are in the very front rank. *S. ternatum*, another American species (from the eastern side of the Mississippi, I believe) can doubtless claim no less merit than the above in so far as its flowers are concerned, but it fails in foliage, whereas those mentioned excel in both.

Now that I am on the subject of American plants I am reminded that one of the most fascinating and lovely exhibits shown at the Royal Horticultural Society's fortnightly shows for a long while was a specimen of *Chimaphila maculata*, the Spotted Wintergreen, which well deserved the first-class certificates it won last month. Though this little North American was introduced as a pyrola nearly two hundred years ago it is still rare, but its beauty is beyond question. It is a wee evergreen shrublet of a few inches with crisp, dark-green leaves, distinctly veined with white. Just above these are raised the flower stems, each of which bear two or three pendulous blossoms, spotlessly white and looking as if they had been modelled in wax. These are scented like our English "May" (Hawthorn) and a plant in full bloom is irresistibly enchanting.

Covering the Flower Garden for Winter Slumber

FLORUM AMATOR

SOMETIME in November, usually the date depends on the latitude, we put the blankets over our hardy herbaceous flower and rose gardens, and around some of our shrubs, and tuck them in carefully there to remain till taken off gradually early next spring. This covering, which is not only a protection against low temperature, but as well against frequent changes in temperature, and furthermore against the burning Winter wind and sun in some cases, must not be put on prematurely, just because we feel that we should like to get the work over with. Too early a covering may heat and sweat the plants and cause the crowns of herbaceous plants to decay, or even cause the buds of rose bushes and shrubs to swell only to be killed later by severe cold.

The plants should be entirely dormant before they are covered. It is well, however, to have the covering material close at hand, as the inevitable time for its use draws near, but better not to put it over or around the plants till the ground is crusted over with frost to the depth of about an inch; then it should be put on at once while the surface is still frozen. Then the covering of frozen soil and the covering of manure or other material, which we place above the frozen soil, acting together not only prevents frost from entering deeply into the ground and freezing the plants to death, but what is equally important, keeps the plants from being killed by alternate freezings and thawings, which take place in Winter in some sections of our country, the thaw causing the buds to swell and the freeze which follows killing them. In short, there are three main points to keep in view in covering our garden plants: First, to wait till they are dormant, and the ground is frozen a little; second, to cover them promptly, so as to keep them frozen and dormant till Spring; and third, to cover the less hardy plants heavily enough, so they may not be frozen to death, but the hardier plants more lightly.

The fact is, many of our herbaceous perennials which are generally classed as hardy, live through the Winter only under the protection of a more or less heavy Winter covering. Not a few, on the other hand, though benefited by a light covering, will live through the Winter without it. To this class belong such plants as the Peony, Achillea, Ægopodium, Aquilegia, Asclepias, Bocconia, Boltonia, Chelone, Dielytra, Dictamnus, Hosta, German Iris, Gypsophila, Monarda, Valeriana, Liliium Candidum, and the hardy Japanese Lilies, and Lily of the Valley.

The true way is to study our hardy herbaceous plants' needs as regards a Winter covering. If we find certain plants winter better under a very thin covering, that is, if they awake from their Winter sleep in a healthier and more robust condition when covered thinly, then we should so cover them each Winter. If we see that other plants come out in Spring from under a mediumly thick protection satisfactorily, that, then, is the proper Winter treatment for them. Again, if certain plants barely survive the Winter under an extremely heavy covering, we should see that each Autumn they have that. Then observations recorded in our note book under the head of: "Winter Covering of Plants" would give us the exact information for which we search garden books in vain. We should not trust these valuable observations to our memory, for we, the observers, may forget them. It is easy

enough to say in a garden book or magazine: "When the ground is frozen an inch or two deep, cover your hardy plants with six to eight inches of coarse manure or leaves and above them lay boughs of evergreen shrubs." In general this is a proper method, such a covering will no doubt be beneficial to the most tender of the so-called hardy perennials, but it may smother others, which perhaps need no covering at all, causing their crowns to decay.

Instead of dumping the covering over our hardy perennials, no matter whether they require a thick or thin protection, it is better by far to place as thick a covering as the plant requires over the entire surface of the ground between the plants and very close up to and around the plants themselves, but a thinner covering of lighter material directly on top of the plant. This method of covering keeps the ground around the plant from alternate freezing and thawing, and the frost from penetrating the ground so deeply as to freeze the least hardy plants to death, but allows the crown of the plant, or the place where the crown is beneath the soil, to get a little light and air through its thinner covering and to start into a strong growth in early Spring before the heavier covering around the plant has to be taken off. Furthermore, when uncovering the garden in the Spring, we can determine exactly where each plant in our garden bed or border is, and will not be likely to break off the crown buds or tender shoots which are just coming out of the ground.

The material commonly used for covering hardy herbaceous plants, including bulbous plants, cannot well be improved on, namely coarse strawy horse manure directly from the stable heap, well rotted horse or cow manure, coarse meadow hay, straw, evergreen tree boughs. It is much better to mix the coarse or the well rotted manure and the leaves together, as leaves alone when beaten down by the Winter rains or weighted down by the snows form too impervious a covering. Evergreen boughs, when they are obtainable, are useful in holding down the leaves, hay or straw, when they are first put on and preventing them from being blown away by the winds. The boughs indeed, if put on thickly enough, are in themselves a sufficient covering for the hardier plants.

Bulbs, especially those which field mice destroy, should not be covered till we find the surface of the soil frozen to a depth of two or three inches. Then they should be covered thickly enough, so that the ground beneath the covering will remain frozen till Spring. This prevents the field mice, which may make their homes in the covering, from digging easily down to the bulbs, and at the same time the bulbs are properly protected during the Winter from frosts.

Rose bushes, especially the taller growing hybrid perpetuals, should be tied closely with some soft material, raffia or soft string, to stakes placed firmly in the ground near them. As soon as the ground freezes a little at night, the soil should be heaped up around them a foot or so high, and after this covering of earth has frozen to the depth of an inch or two, the entire bush, in case of the teas and hybrid teas, should be covered with coarse manure, leaves, hay, evergreen boughs, whichever of these is most available. The hybrid perpetuals will probably be too tall to cover in the same way as the teas and hybrid teas, but straw

or burlap may be tied closely around them and the stout stake also which supports them. As regards the rambler and climbing roses in sections where the temperature goes so low as to kill back badly the long shoots of the Summer's growth, each shoot as Winter approaches may be formed into a coil, but not so small as to break the shoot. The coils may be laid together at the foot of the bush and covered with soil and coarse manure or other material.

Half hardy deciduous shrubs and dwarf evergreens, whose branches hold the snow and are liable to be broken down by its weight, should have one or more strong stakes placed firmly in the ground near them, and the shrubs and evergreens tied to them more or less closely as they require. The surface of the soil around them should then be heavily covered with the usual materials for such a purpose, and if the deciduous shrub is rather likely to be killed back more or less in Winter, the covering may be heaped around its main stem well up to where the lower branches put forth.

This broad leaved evergreen needs to be prepared for Winter in a somewhat different way than rose bushes and other deciduous and evergreen shrubs. In the first place, unless the soil, in which they are growing, has been thoroughly soaked deep down by copious Autumn rains, it will have to be watered with a hose or buckets. Rhododendrons cannot retain their foliage in good condition during the Winter, if they enter the Winter season with their roots dry. Some advocate, when artificial watering is necessary, that before the water is applied, numerous deep holes be made with an iron crowbar among the rhododendrons or, in the case of a single specimen, around it, since this will cause the water to go down directly deep among the roots. After the soil is well soaked, either by the rains or artificially, a heavy covering of leaves or manure, or both, should at once be put around the shrubs. Lastly a shelter formed preferably with evergreen boughs (red cedars are also excellent for this purpose) set in the ground firmly, or by boards nailed to posts, must be given the rhododendrons on the south to shelter them from the Winter's sun, and on the north to keep off the biting Winter wind. Of the two the southern barrier is the most important. If the rhododendrons are in beds, the evergreen boughs or small cedars may be stuck in the ground around the beds and in between the shrubs. If, however, the shrubs are growing in such a position that evergreen trees, or even large deciduous trees, shield them in a considerable measure from sun and wind, the barriers of boughs or boards are not necessary.

THINGS AND THOUGHTS OF THE GARDEN

(Continued from page 246)

L. *Harrisi* is reported to be larger and of finer quality than for a number of years, and there are also stocks of Creole and other lilies offered by some of our Southern growers, so that we shall probably get a fairly good supply for Easter after all. How we shall fare with the various forms of *Speciosum* and *Auratum* remains to be seen; no doubt these will be late also, and as the bulk are used for outdoor planting rather than forcing late arrivals mean later plantings. A good covering of leaves or straw will, however, exclude frost so that it will be easily possible to plant these late arrivals even in late December or January, which will be preferable to carrying them over Winter in pots.

* * *

The present Summer has been one of the driest on

record. In Boston only .34 of an inch of rain fell in September and with an accumulated deficiency of the year of 9 inches, it is not surprising that many cities, towns and villages are in serious straits for water. As the drought came in late Summer, the effects on vegetation are not nearly as apparent as if it had come earlier and crops of both fruits and vegetables are extremely good; the Autumn tints on trees and shrubs are also very fine. Lawns, unless watered, are a veritable eyesore with their accumulations of noxious weeds and it has surely been a hard season for new seedings. The continued dryness will assure us well ripened wood on deciduous trees and shrubs, but it is very serious for evergreens, more especially those more recently planted, and copious waterings should be given these to save them. It is of little value to pour water on the hard surface but if a basin with a good rim of earth round it circles each plant and this is filled with water once or twice, and later the dry earth is pushed back, we may rest assured that the roots are damp. It is especially necessary that all evergreens have their roots wet ere the ground freezes up or we can safely look for a big death list next Spring, particularly if the ground should remain hermetically sealed as sometimes happens for many weeks.

LILIES FOR EVERY GARDEN

(Continued from page 251)

some well-known tunes sung until they become hackneyed, but the very charm of the tune was the reason of its popularity. Grouped with grey bee-balm and pale yellow day lilies (*hemerocallis thunbergi*) their odd pinkish orange color is at its best. *Speciosum* are planted in the phlox clumps which they follow and alongside blue salvia. *Martagon album* in partial shade against a bank of ferns are dainty and hardy. In a nearby rock garden there are quantities of *philadelphicum* which were transplanted from the fields bordering on the woods to a dry, semi-shady place where they are doing very well.

I urge every one to plant lilies. Start with a few and you will not regret it. Try some kinds new to you. There is no thrill for the gardener like seeing a hitherto unknown flower opening where he can watch it. Lilies glorify the garden as no other flowers do. Whether it is because the lily has been associated with sacred subjects in pictures, tapestries and statues, or solely because of its beauty there is something of a spiritual quality about most of them.

AUTUMN

The yellow year is hastening to its close;
 The little birds have almost sung their last,
 Their small notes twitter in the dreary blast—
 The patient beauty of the scentless rose,
 Oft with the morn's hoar crystal quaintly glassed,
 Hangs a pale mourner for the Summer past,
 And makes a little Summer where it grows;
 In the chill sunbeam of the faint brief day
 The dusky waters shudder as they shine,
 The russet leaves obstruct the straggling way
 Of oozy brooks, which no deep banks define,
 And the gaunt woods, in ragged, scant array,
 Wrap their old limbs with sombre ivy-twine.

Coleridge.

Self-Sown Biennials

TO every amateur who works with his own ten digits and not by the proxy of a professional gardener there comes a time, I fancy, soon or late, when his spontaneous energy is less than it once was, and the passion for muscular toil sensibly abates; when, in short, he is disposed, in respect of garden work, to accept the advice to "moderate his transports." It is then one learns to regard with a preference—half gratitude, half affection—those easy plants which give little trouble—bulbs which come up year after year without abating a jot of their beauty, herbaceous plants which require neither annual manuring nor periodic transplanting, shrubs that want nothing for their well-being but abundance of space, and things, annual or biennial, that see to their own propagation and require on your part nothing more arduous than judicious thinning with the hoe. About these last a word may be permitted by way of suggesting to brother gardeners, whose vertebral column is possibly not the elastic thing it once was, one or two plants of this easy class which will well repay the little trouble of growing them; not so much about annuals, however, as about some half-dozen biennials which are worth while and which require only a first foothold to become permanent denizens of the garden. Though, if it comes to that, there is no lack of desirable annuals with this same valuable quality of permanency; for, however tender and beautiful an annual may be, there is somewhere a country where it sows itself one year to come up the next, where, in other words, it is a weed. *Nigella*, *Centaurea*, *Iberis*, *Nemophila*, *Clarkia*, *Alyssum* are weeds in the country of their nativity and may become weeds in any garden where slugs permit. A biennial, however, is another thing, being, as a rule, of larger stature and more stately habit, and requiring, in consequence, two years to build up its system and compete the cycle of its growth. One of large size and imposing appearance, is the tall Evening Primrose (*Oenothera biennis*). This beautiful and interesting flower has been a standing feature in my garden for ten years and more. It comes up here and there in the borders in unexpected places—often, of course, where it is not wanted, but often also, I must do it justice to say, precisely where I should have wished it to be if I had thought the matter out. In any case, if it should come where you do not wish it to be, a touch of the hoe is sufficient. On the other hand, should you wish to have it in any spot where it has not chosen to come, few things are so easy to transplant. The endurance of the plant is wonderful. Dry weather or moist, your transplanted *Oenothera*, after wilting for a day or two, will brace up and look as lively as if it had sown itself where you had placed it. The beauty of the Evening Primrose is sufficient to recommend it if it had nothing else, but, for me, one of its attractions is its evident delight in life and growth. I had rather see, for my part, a Dock or a Thistle grow as if it enjoyed life, than the most precious stove or alpine treasure that lingers out a coddled existence; though, for all that, I do not deny the satisfaction there is in coaxing a sick plant back to vigorous life. Every hospital nurse knows this kind of triumph. But there is no room for coaxing or coddling with *Oenothera biennis*. Wet does not harm it, neither does drought; it seems to prefer exactly the conditions of soil and weather it happens to get. It is subject to no parasites, blights or diseases that

I have ever seen. It stands erect without support; or if the wind does happen to twist off a branch or two, these are not missed—there are so many left. But, after all, the distinction of this, as of all Evening Primroses, is that it is a flower of the dusk, one of the far from numerous vespertine group which wake to full activity only when Marigolds, Daisies and other drowsy composites are folding their petals to rest. Night moths, which are so drawn to light in darkness, must certainly frequent the flower, though I do not know which they are. When the evenings begin sensibly to lengthen, and the air has an eager tang, which, though pleasant, is a premonition of something more nipping and less pleasant yet to come, my own otherwise modest garden becomes for a time almost flamboyant, lit up as it is from end to end with Chinese lanterns—that is to say, with lingering blooms of many-colored single Hollyhocks swinging on their wands to the wind, but chiefly with the vesper lamps of *Oenothera biennis*, which flop open one by one while the light is waning, as if fairy Mrs. Gamps were unfurling their umbrellas. Those who grow these *Oenotheras* must have observed how punctiliously they observe their times and seasons—how, in opening their first blooms, the various plants synchronize (there is no other word) as regards not merely the hour, but the day and the month, possibly even the minute. Scattered plants, separated possibly by considerable distances in a large garden, will burst into bloom with a wonderful unanimity, at the same hour of the same day of the three hundred and sixty-five. Finally, to complete its tale of virtues, this flower has a pleasant fragrance—not obtrusive, but faint and elusive rather, as befits the crepuscular hour, yet sufficient sometimes to cloy the air a little, for the perfume is of the rich exotic kind which we associate with such things as Orange Blossom, Jasmine and Stephanotis.

Another fine biennial which may be trusted to hold its own when once introduced, is the Giant Sea Holly (*Eryngium giganteum*). I suppose we must regard all the Sea Hollies as umbellifers. But to eyes like mine, which look to the appearances of things rather than to their hidden affinities, this *Eryngium* has the Thistle attributes raised to a high power, except stature, perhaps, for I do not suppose that the height even of luxuriant specimens is much over 3 feet. But the completeness of its holly-like apparatus for self-defence, its mathematical grace and symmetry of shape, and the veined silver of its leaves seem to assign it a place among those things which "none may molest with impunity." One must not, however, in this biennial, look for the steel-blue which is the conspicuous beauty of stem and flower in so many *Eryngiums*. Silver is its metal, not steel, simulation of frosty silver being its outstanding feature, the most successful mimicry of the metal known to me among many silvery plants. I have spoken, erroneously perhaps, of this flower as a biennial, since it might possibly be, more correctly described as a triennial. Grown under exceptionally favorable conditions, the Giant *Eryngium* may flower the second year from germination, but I do not think many of mine, if any, do so. In this, the third year of one batch, there has been a great display of flowering heads—leaving many, however, for next year, which, when they come, will, properly speaking, I suppose, be quadrennials.—*The Garden*.

Foreign Exchange Department

KNIPHOFIAS.—The effectiveness and brilliance of Kniphofias in the scarlet border, or the mixed herbaceous border, during August and September is well known, and these striking Autumn flowers should be largely grown for these purposes.

They are, however, even more effective when grown in large masses in the wild garden where they may be given prominent positions, as they are magnificent when in flower and in Winter their dark green leaves are quite attractive. They revel in an open position in full sunshine, where their torch-like spikes are seen at their best and produce a wonderful blending of yellow, orange and scarlet with a soft "bloom" thrown over these brilliant shades. Planted in bold groups their effect is visible from a long distance, so that they are plants of much value to the landscape gardener.

K. aloides and the varieties *grandis*, *nobilis* and *longiscapa* are all particularly handsome, and well worth growing, as also are many of the hybrids such as *Obelisque* and *Ophir*, which have handsome yellow and orange spikes of flower 6 feet or 7 feet high. There have been many varieties of Torch-Lilies introduced during the last twenty years, but probably seventy per cent. of them are traceable to *K. aloides*, itself a plant capable of yielding very fine effects either planted in quantity, alone, or grouped with other suitable vegetation.

Kniphofias grow well in a good, medium, sandy loam and appreciate liberal, annual top-dressings of manure. The soil should, however, be well drained, as, although these plants like plenty of moisture during the Summer, anything approaching stagnant moisture at the roots is inimical to them, and is frequently the cause of losses during the Winter.

Kniphofias may be increased by division in the Spring, but it is not wise to disturb the old plants more than is really necessary. Seed is produced fairly freely from the bases of the earlier flower spikes, and affords an additional means of propagation.—*Gardeners' Chronicle* (British).

BOISSIER'S GLORY OF THE SNOW.—*Chionodoxa Lucillia* has long been known as one of the most charming of the Glories of the Snow, and ever since its introduction it has been recognized as one of the most charming of our Spring flowers. It is not generally known, however, that the form in general cultivation is not the same as the one originally found by Boissier and described by him in glowing language. The *Chionodoxa* named *Lucillia*, which was first introduced, flowers a little earlier and is not such a fine blue as Boissier's plant. Within recent years the latter has come into commerce and is one of the most delightful of all. It resembles the other in the possession of a large white centre, but the blue which surrounds this is much deeper, yet of great brightness. Tastes will not agree in everything and there may be some dissent from my view that Boissier's variety is superior to what is known as the type. It may be cultivated with advantage, either in clumps or masses in the rock garden or grass or in the front of the border. Bulbs are not expensive and may be obtained from most bulb dealers and planted at a depth of 2 ins. to 3 ins. as soon as obtained. Boissier's Glory of the Snow also makes a good pot plant, putting the bulbs almost close together and bringing on slowly in a cool house, or, better still, plunging the pots outside and bringing them in as soon as the plants show flower.—*The Garden*.

THE GLADIOLUS AS A DECORATIVE CUT FLOWER. The value of the *Gladiolus* as a decorative garden flower has been realized for many years, but, chiefly owing to its size, it has never been seriously considered as having any particular merit as a cut flower for indoor decoration. However, the improvement of the *primulinus* hybrids has now, to a large extent, removed the disadvantage of unwieldiness possessed by the *Gandavensis* section, though the latter type still holds a very high place in decorative schemes on a large scale, such as ballrooms.

The main points in favor of the *primulinus* hybrids are beauty of coloring, and shape of flower, gracefulness of spacing of the blooms on the spikes, and slenderness of the spike itself.

In glass bowls, with *Gypsophila*, the spikes may be arranged quite easily, to give a very beautiful effect. The straight, stiff, sword-like spike of the *Gandavensis*, with its mass of closely set flowers, does not show to advantage and, should any spike come away from the perpendicular to any degree, the whole beauty of the flower is lost. With the *primulinus* hybrids it is different; the graceful curves of the slender spikes and the peculiar shape and placing of the flowers themselves, both lend beauty to a bowl.

August and September often present difficulties in the way of indoor floral decorations, which these *primulinus* hybrids go far to overcome. The initial outlay is not great, the flowers themselves are no trouble to grow, and their beauty and value for Autumn decoration will be readily realized by all who cultivate them.

[Our correspondent does not refer to the value of the smaller-flowered varieties for floral decorations indoors. These, however, are exceedingly beautiful. Eds.]—*Gardeners' Chronicle* (British).

THE ORANGE-FLOWERED BITTER VETCH.—Falling over a large boulder the orange-yellow flowers of this plant are very attractive, the color unusual among this class of plants. Unlike the Spring Bitter Vetch (*O. vernus*), which grows little more than 9 inches in height, this handsome kind reaches 2 feet or more and is suitable for positions as above described. This plant requires to become well established before commencing to flower freely, after which it needs very little attention. It blooms during May and June, and I was pleased to see a vase of its pretty flowers in one of the exhibits at the Chelsea Show.—*Gardening Illustrated*.

HEUCHERAS.—Heucheras are not grown so much as they deserve to be, and from gardens where one would expect to find them they are absent. Planted in clumps about a border they are charming in their season of blooming, and the slender spikes of flowers contribute not a little to the beauty of a garden. This season I have used the spikes as adjuncts to vases of other flowers, and they have been much admired. Perhaps still the best-known of the Heucheras is the old *H. sanguinea*, with coral-red flowers. Edge Hall is a salmon-pink, very pretty, whilst *Flambeau* (deep red) and *Nellie* (light pink) are worth inclusion in any garden.—*Gardening Illustrated*.

THERMOPSIS.—Though a rampant grower and a very aggressive spreader, so that it needs care in planting, this is a very valuable plant for the Spring, and I find it comes in very well for house decoration, its spikes of yellow Lupin-like flowers combining very well with blue and white Lupins in a tall vase. I find it a very attractive plant, and if one can give it plenty of room it will need no care whatever, but go on happily year after year, giving an abundance of spikes of deep, clear yellow, Pea-shaped blossoms. It is a true friend to a busy gardener because of its contented habit. Another great point in its favor is that it needs no staking, nor have I ever found it subject to insect pests.—*Gardening Illustrated*.

SCABIOSA CAUCASICA.—If I were limited to six sorts for cutting I would certainly include the Caucasian Scabious. More especially would I choose some of the seedling kinds which show a decided improvement in color and form. There is a varietal form which produces immense flowers of a much deeper shade than the type. This sort or a variation from it appears under various names in different catalogs, but it is advisable to make sure of securing a really good strain. The hardness of this Scabious is beyond question. It is quite true that the plants have a way of dying off in the Winter, but this is invariably due to excessive moisture. In heavy retentive soils in Devonshire this plant frequently succumbs in the Winter, but I have known of large plantations in a Yorkshire nursery where losses rarely occurred even in the most rigorous of Winters. It is really a question of giving them a fairly light and well-drained soil. Well-rotted manure may, of course, be generously supplied, and this appears to be a necessity in order to secure an abundant supply of good long-stemmed blossoms.

This Scabious may be easily propagated from seeds, and it is advisable to raise a batch of seedlings now and again to provide against accidents. Seeds may be sown now under handlights in a light sandy compost containing a plentiful supply of leaf-mould. The lights should be removed during the Summer and replaced in the Winter. The seedlings may be transplanted to their flowering quarters the following Spring. I do not wish to dogmatize in this matter. I mention this course of procedure as being the one I prefer to follow, and which I have found most suitable to the conditions prevailing in a Devonshire garden. Others prefer to sow in the Autumn, and doubtless they achieve an equal measure of success by so doing. The older one gets the more does one realize the futility of attempting to lay down hard and fast rules in gardening matters. Most of us are able to call to mind instances where orthodox systems have failed while methods which the trained gardener would avoid have been attended by success.—*Gardening Illustrated*.

PINKS: OLD PLANTS VERSUS NEW.—I find there is a certain amount of sentiment in the minds of many folk who grow Pinks in their gardens that is seldom associated with other early Summer-flowering plants, and is somewhat difficult to appreciate. For instance, how often one notices in gardens miniature beds of Pinks that long since have outgrown the space they originally occupied. It was never intended that they should rob ground belonging to other plants and to smother them, but owners of these gardens "could not find the heart," so they have told me, to limit the growth of their sweet-smelling favorites, and so Mrs. Sinkins and the rest of them have gone on from year to year unmolested. It almost inevitably happens that a day comes when at the centres of these "rings," or small beds, canker shows itself, and it quickly spreads, the result being that the flowers are poorer in quality each succeeding year. To keep up a healthy stock and to ensure Pinks

of good quality the better plan is to propagate a certain number of plants from cuttings every season after they have done blooming, and I venture to say that one obtains a more prolific display from younger plants than from huge masses undisturbed year after year.—*Gardening Illustrated*.

THE TWO-FLOWERED EVERLASTING PEA (LATHYRUS GRANDIFLORUS).—Remarkably handsome at the present time is this large-flowered species, which revels in almost any position. A few plants put in at the foot of a pergola have grown into quite a colony, and, scrambling up the battens and among the single white Roses of the pergola, the profusion of flowers is unusual and very beautiful. The wiry growths are 6 feet or more in height, and sprays of them have fallen into the inside of the pergola, which is built upon a retaining wall, and these hang down the wall in a picturesque way. The rosy-purple flowers are the largest of any of the Everlasting Peas, and the plant is among the hardiest. The flowers are always borne in pairs. All the attention this beautiful plant requires is the removal of its old growth in Autumn and a little top-dressing if extra vigorous growth is desirable. If planted near a trellis or similar support it will affix itself in a charming manner, without the necessity of either tying or training. Rough branches also form excellent supports. All the perennial Peas are well worth a place in the garden for, in addition to their unusual beauty and charm when used to grace trelliswork and other rough supports, they give us delightful pictures when planted on grassy, sunny slopes, with their flowery growths spreading out in all directions.—*Gardening Illustrated*.

DIGITALIS.—Wild Foxgloves seldom differ in color, but cultivated ones assume a variety of colors, including white, cream, rose, red, deep red, and other shades. The charm of these varieties, however, lies in their pretty throat markings—spots and blotchings of deep purple and maroon, which make large flowers resemble those of a Gloxinia; hence the name *gloxiniæflora* is applied to some finely-spotted kinds. The garden plants make grand border flowers; they are more robust than the wild plant, and have stouter stems and larger blooms. If associated with other tall plants they look well as a background to mixed borders; and the improved varieties have a fine effect in the wild garden if planted or sown in bold masses. They are good, too, among Rhododendrons, where these bushes are not too thick, and they charmingly break the masses of foliage. The seed is small, and is best sown in pans or boxes, under glass, early in May. When the young plants are well up they should be placed out of doors to get thoroughly hardened before being finally planted out. In shrubby borders varied clumps of several plants produce a finer effect than when set singly. The Foxglove frequently blooms two years in succession, but it is always well to sow a little seed annually, and if there be any to spare it may be scattered in woods or copses where it is desired to establish the plants. Those who do not require seed should cut out the centre spike as soon as it gets shabby, and the side shoots will be considerably benefited, especially if a good supply of water be given in dry weather. In a good variety a side shoot will supply an abundance of seed.—*Gardening Illustrated*.

PLANTING HARDY BULBS.—The bulb season has returned, and with it the usual catalogs, with their tempting offers of choice varieties of Narcissi, Tulips, Hyacinths, Crocuses, and many other scarcely less attractive subjects.

The purchasing of bulbs is frequently delayed, to the disappointment of the purchaser. The bulbs that ripen first come earliest to the market, and are usually of better quality than those that ripen later. Further, deterioration in store, although not rapid in the earlier part of the season, is nevertheless, a factor, and it increases as the season advances. The growth which actually takes place in Crocus, Hyacinth, and Tulip bulbs while they are in the store affords sufficient proof that the store-room is not the place for them to pass the Autumn in, however well they may have passed the time there in the later Summer months since they were harvested. The best advice that can be given to those who would have a creditable display of bulbous flowers next Spring is to buy early and plant early.

Hardy, Spring-flowering bulbs are amongst the cheapest of garden plants; they produce a floral display of surpassing splendor if cultivated with reasonable skill, and the planter may indulge in the greatest variety without incurring an extravagant outlay.

Where geometric arrangements of beds are to be planted with bulbs, a few sorts will be preferable to many, but in borders a wider range of varieties may be employed. The choice of varieties is largely a matter of individual taste, but for a small formal garden a combination of yellow and scarlet flowers produces a brilliant effect.

One of the greatest recommendations of early bulbs for furnishing the formal garden is that their growth is completed before the season of Summer bedding, and by the end of May the bulbs are so far ripe or ripening that lifting does not seriously harm them.

Apart from bedding schemes carried out with flowering bulbs,

every garden offers great scope for the use of these plants in a variety of ways. Planted in quantity and variety in grass and in the more open spaces fringing the shrubbery, they are beautiful and attractive and a source of much pleasure.—*Gardeners' Chronicle* (British).

SCENTED LUPINE.—Sheer amazement is the only feeling of which one can be conscious when standing before an exhibit at a flower show of the modern Lupin in its full glory, a sensation that is only intensified when memory begins to work and recollection of the varieties of but a few years back comes vividly before the mind. Who could or would have supposed that so much latent possibility lay behind the modest spikes of white, blue and purple, with which we were all so familiar? It was a beautiful flower then (when it did not disappoint by shedding a good third of its buds unopened), but today words absolutely fail to convey any adequate picture of the marvellous range and beauty of the colors displayed. This, however, is not all. Nature, when she is encouraged by the hand of the hybridist, is apt to overflow with bounty and in the case of the Lupin she has, as her latest and best development, given us a series of perfumed forms. This is not a faint washy odor, but a delicious and unmistakable perfume that fills the air all round where they are growing. The color range is not restricted in this remarkable break, for every shade of white, blue, mauve, purple, crimson, pink and yellow is represented and one is only left wondering what surprise this remarkable plant can now have "up its sleeve" for us.—*The Garden*.

Brief Horticultural Jottings

We are accustomed to think of all the big fruit orchards of our country as being on the Pacific side of the continent and it may come as a surprise to a good many to know that little Vermont lays claim to the biggest orchard in the world. It is the property of Edward H. Everett and since plantings were begun in 1911 no less than 50,000 apples and 15,000 other fruits consisting of pears, quinces, cherries and plums have been planted. The ultimate goal is 100,000 trees, which will occupy over 3,600 acres of land. Many of the rows are a mile in length. Each row is given a letter and each cross row a number, so that each tree can have its specific identification. This great orchard in the Green Mountain State is in Bennington and is managed in a thoroughly up-to-date and scientific manner.—*W. N. C.*

* * *

St. Dorothy, patroness of gardeners, was a virgin martyr of Cæsarea, Cappadocia, martyred under Diocletian about A. D. 303. February 6 is the usual day dedicated to her, but at Arles the date is March 28. According to the legend, she was asked by a lawyer, Theophilus, to give a sign while undergoing torture; upon her prayer an angel appeared bearing three apples and three red Roses. She was then beheaded, and after her death the angel returned to Theophilus bringing the fruit and flowers as a gift from St. Dorothy, whereupon he was converted and martyred also. In art she is depicted holding a sword, with the Apples and Roses at her side or in her hand.—*Florists' Exchange*.

* * *

We learn from the *Journal of the Royal Society of Arts* that a company in the Philippines has recently begun the manufacture of paper from the husks of coconuts, of which it is estimated that 350,000 to 400,000 tons are wasted annually. The present cost of production is high, and it will be necessary to convert the husks into pulp near the mill from which they are a by-product, in order to save expense in transportation. Even then it is questionable if the pulp can be produced at a figure that will allow it to compete with wood pulp, or other kinds of pulp now used for paper making. Other uses to which the coir fibre is put are rope making, filling mattresses, etc., and the making of corky pulp for insulation purposes.—*Gardeners' Chronicle* (British).

* * *

In a field in Madison county, Iowa, stands a monument which was recently dedicated to an apple tree. This tree is the parent tree of the now famous Delicious apple. After a life of fifty years the tree still stands and bears abundantly. The offspring, in trees distributed and planted, number more than 7,500,000, according to the lowest estimates by experts, and fully one-third of the baby trees have survived and grown to a producing age. The estimated value of the annual crop of apples brought to the market from these trees is \$12,000,000. Therefore, the 50-year-old tree, near which has been placed the memorial, a granite boulder suitably inscribed, may call itself the \$12,000,000 apple tree.—*Florists' Review*.

National Association Of Gardeners

Secretary's Office, 286 Fifth Ave., New York

The aims of the association are to elevate the profession of gardening by improving conditions within it.—To cement a closer bondship among all engaged in, and interested in, gardening—to create a greater confidence between employer and employee.

Co-operating with the Massachusetts Agricultural College, the association conducts a course in training young men for the profession, whereby they obtain theoretical knowledge as well as practical experience.

SERVICE DEPARTMENT

The National Association of Gardeners operates a Service Department to serve country estate owners in an advisory capacity in adjusting problems which occasionally arise in the maintenance of country estates.

Owners desiring the services of gardeners, thoroughly versed in all phases of the profession and qualified to assume the responsibilities the position calls for, as superintendent or gardener, should apply to this department.

OFFICERS 1923

President JOHN BARNET, Sewickley, Pa.	Vice-President ROBERT P. BRYDON, Cleveland, O.
Secretary M. C. EBEL, New York, N. Y.	Treasurer MONTAGUE FREE, Brooklyn, N. Y.

TRUSTEES (For 1923)—Thomas W. Head, D. L. Mackintosh, Arthur Smith, New Jersey; Robert Cameron, Massachusetts; Andrew L. Dorward, Rhode Island.

DIRECTORS—(To serve until 1924) William Hertrick, California; George H. Pring, Missouri; Robert Weeks, Ohio; Thomas Wilson, New York; Harold Bryant, Connecticut; Harry Cartwright, Michigan; H. Ernest Downer, New York. (To serve until 1925) George Wilson, Illinois; James Stuart, New York; William Kleinheinz, Pennsylvania; Edwin Jenkins, Massachusetts; Carl N. Fohn, Colorado; Joseph Tansey, New York; John Tonkin, Pennsylvania. (To serve until 1926) Alexander Michie, New York; George F. Stewart, Massachusetts; Theodore Wirth, Minnesota; George W. Hess, District of Columbia; R. P. Brydon, Ohio; William C. Rust, Massachusetts; Charles Schroll, Wisconsin.

SUSTAINING MEMBERS

Candler, Jr., G. Gamby Jordan. *South Carolina*—Robert S. Mcbane.

LOCAL BRANCHES

NEWPORT, R. I.: Andrew L. Dorward, chairman; Frederic Carter, secretary.

ST. LOUIS, MO.: George H. Pring, chairman; Hugo M. Schaff, secretary.

NASSAU COUNTY, L. I.: James Duthie, Oyster Bay, chairman; John McCullough, Oyster Bay, secretary.

BOSTON, MASS.: Robert Cameron, Ipswich, chairman; W. N. Craig, Weymouth, secretary.

WESTERN PENNSYLVANIA: Manus Curran, Sewickley, chairman; Henry Goodband, Sewickley, secretary.

CLEVELAND, O.: R. P. Brydon, Farmington, chairman; Arthur Brown, secretary.

NORTH SHORE OF ILLINOIS: James A. Wilson, Lake Forest, chairman; E. P. Coe, Glencoe, secretary.

MONMOUTH & ELBERON, N. J.: Thomas W. Head, Red Bank, chairman; Arthur Brown, Elberon, secretary.

NORTH FLORIDA: Herbert Tickner, Orange Park, chairman; Alfred Addor, Jacksonville, secretary.

HOW THEY DO IT

A Massachusetts member on reading the report of the Pittsburgh convention in the GARDENERS' CHRONICLE and noting on the list of attendants the names of men who seldom miss an annual meeting, wrote to inquire how they do it, while commenting on the fact that he had not been able to leave the place for a day since the Boston convention last year. In answering this member, the secretary replied that these men regard themselves as equally entitled to an annual vacation as are men in other fields of endeavor, and that it has been his observation that there are few employers who will deny their gardeners a holiday in order to attend the annual meeting of their association if the matter is presented in a proper light, for they become equal beneficiaries. The days are not wasted recreation. Traveling tends to broaden one's view, while meeting with one's fellow gardeners from all parts of the country for an interchange of ideas tends to increase one's knowledge.

THE NORTH FLORIDA BRANCH

The following gardeners, H. W. Tickner, of Orange Park; Leon C. Eldredge, Michael Salmen, Gus Gottschlich, J. K. Brower and Alfred Addor, all of Jacksonville, met at the home of Mr. Tickner on September 17 for the purpose of organizing a local branch of the National Association of Gardeners, to be known as the North Florida Branch. H. W. Tickner was elected chairman and Alfred Addor secretary and treasurer.

The meetings will be held regularly the third Friday of each month in the different members' homes. Each member is assessed dues of fifty cents a month. After some lengthy discussion of a more or less business nature, it was moved and seconded that we accept invitations from garden clubs to give them information regarding garden work. Michael Salmen and Gus Gottschlich were named as a committee to inquire into the advisability of making an exhibit at the coming Florida State Fair and Show in Jacksonville during November.

An expression of thanks was tendered to P. W. Popp, of New York, who was present at the meeting and helped us with suggestions as to the course to follow. After the meeting had adjourned, an inspection of the Ferguson and Johnson estates followed.

ALFRED ADDOR, Secy.

CLEVELAND BRANCH

The Cleveland Branch of the National Association met at the Alhambra Restaurant on Sept. 4. Three new members were endorsed. This Branch was formed April 30, 1923, and has held four meetings, endorsed seven applications for membership in the National Association, and has been instrumental in securing several sustaining members. Up to date the Branch has twenty-five members.

The evening was spent in discussing various subjects, including the Pittsburgh Convention and the coming National Flower show and conference. Adjourned to meet at the Mrs. F. F. Prentiss Est. (Robert P. Brydon, Supt.), Monday evening, October 29.

A. BROWN, Secy.

NORTH SHORE OF ILLINOIS BRANCH

The third meeting of the above branch was held at the home of James Wilson, of the H. B. Clow Estate at Lake Forest, on Sept. 19. Considerable discussion on Article III, Sec. 1 of the Constitution and By-Laws was taken up and the ten members present suggested that it be either revised or done away with. If not they believed it was going to be hard to reinstate some old members. (This By-Law refers to members suspended for non-payments of dues, having to pay past indebtedness to the association before reinstatement). Thomas Dobbin, of the Farzau Estate, Highland Park, joined up with this branch. Four new applications were received and will be voted on at the next meeting to be held on Oct. 18 at the home of the secretary at Glencoe. A pleasant evening was spent in discussing garden and other topics, and after partaking of Mr. and Mrs. Wilson's hospitality, the meeting adjourned.

J. R. CLARKE, Secy.

LETTERS OF APPRECIATION

The following are extracts from letters received by the secretary:

"I should like to become a sustaining member of your association but do not know the procedure, dues, etc. I always read the GARDENERS' CHRONICLE and approve of the work you are doing.

"Sometime through your Service Department, I may secure a more enlightened type of head gardener than I now have."

"I enclose check for ten dollars for sustaining membership in the association.

"I wish to take this opportunity to thank you for recommending ——— to me. Mrs. ——— and I are delighted with him and his family, and do not see how we could be more pleased with anyone."

"My head gardener here has called my attention to your association by giving me to read the September number of the GARDENERS' CHRONICLE. I shall be glad to be enrolled as a sustaining member and enclose my check for ten dollars to cover membership fees."

NEW MEMBERS

Sustaining: Mrs. Jesse I. Straus, Mt. Kisco, N. Y. (Fred W. Sparks, superintendent); Clarence L. Hay, Newbury, N. H. (Percy Plumeridge, gardener); E. J. Dives, Reading, Pa. (Frank Jenkins, gardener); James Parmelee, Painesville, O. (George Wyatt, gardener); Mrs. Clement S. Houghton, Chestnut Hill, Mass.; Mrs. Edward S. Harkness, New London, Conn. (Stanley Jordan, superintendent); Mrs. S. Brinckerhoff Thorne, Greenwich, Conn. (Angus G. Ross, superintendent).

Active: Miss L. Jacques, Cleveland, O.; Walter Cox, Youngstown, O.; Andrew Ferguson, Madison, N. J.; Robert A. Chesney, Montclair, N. J.; Leon C. Eldredge, Gus Gottschlich, Jacksonville, Fla.; J. T. Patterson, Atlanta, Ga.; Adrian P. Wexel, Ann Arbor, Mich.

Associate: Charles F. Irish, Cleveland, O.

LOCAL SOCIETIES

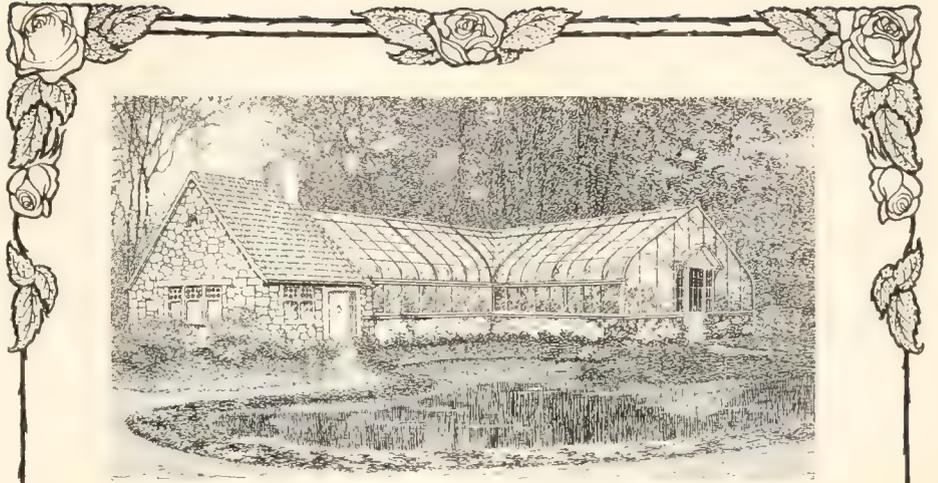

WESTCHESTER AND FAIRFIELD HORT. SOCIETY

The regular monthly meeting of the above society was held in Greenwich, Sept. 11. An invitation was received from the committee in charge of the Cos Cob Fair asking the society to help the fair by making an exhibit. In the monthly competition, W. D. Robertson received first for a specimen *Adiantum cuneatum*; Edwin Beckett, second, for a *Cattleya Fabia*. For fruit and vegetables, John Wilson was first with a collection of fruit; H. F. Bulpitt, second, with a collection of vegetables; James Linane, third, with cauliflower. James Linane gave a talk on vegetables, which was very interesting and provoked considerable discussion. James Stuart gave an interesting account of the convention of the National Association of Gardeners, which he said was the best he had attended so far.

The twelfth annual flower show of this society held in Greenwich Sept. 12, 13, 14, was well attended. In spite of the prolonged drought which has seriously affected gardens hereabouts, the exhibits in Dahlia classes though not as large as at previous shows, made a very good showing. The exhibits of flowering and foliage plants were very good. Mrs. Whitelaw Reid, of Purchase, received a gold medal for a display of Orchids. Mrs. F. A. Constable, of Mamaroneck, received a silver medal for a group of flowering plants. Mrs. E. E. Smathers, of Port Chester, was awarded a silver medal for a choice group of foliage plants.

Among the winners in the private classes were: Mrs. F. H. Allen, Pelham Manor; Mrs. F. A. Constable, Mamaroneck; Mrs. Whitelaw Reid, Purchase; Mrs. E. E. Smathers, Port Chester; Mrs. E. H. Hooker, Mrs. W. Heacken, Mrs. J. A. Topping, Mrs. Luther M. Werner, of Greenwich.

For the collection of twelve vases of hardy herbaceous perennials, Mrs. E. E. Smathers was first. Mrs. Whitelaw Reid was first for the twelve vases of annuals. As usual, there was keen competition in these two classes. In the classes for Palms, Ferns and Foliage plants, Mrs. E. E. Smathers and Mrs. F. A. Constable were principal winners. Mrs. F. H. Allen won the silver cup donated by Andrew Kennedy, Inc., for twelve varieties of vegetables, Mrs.

This house with its attractive curved eaves and enduring steel frame was designed especially to fit a location, within a stone's throw from the residence.

**Greenhouse Convincement
What, Therefore, Is It?**

Always, in whatever you buy, there are two influencing factors. One—what the makers claim for the thing they make, the other—what the buyers of that thing say. With most careful buyers, claims about what *can be done*, carry far less conviction, than evidence of what *has been done*.

If you are one of the latter, we have, in conviction, greenhouses on the finest estates from Maine to California. Green-

houses, that were not merely built by us, but painstakingly designed to fit into the landscaping. They successfully combine the attractive with the thoroughly practical.

For considerably over half a century, we have been greenhouse specialists. Always, our Designing Department is at your disposal. To our printed matter you are most welcome. On your special request *only*, will a representative call.

How Constructed

All our four constructions have complete steel frames, either with or without metal mounted glazing bars

- 1. Curved eaves with steel frame and cypress glazing bars.
- 2. Curved eaves with steel frame and galvanized steel U-Bar glazing bars.
- 3. Curved eaves, steel frame with galvanized steel V-Bar glazing bars.
- 4. Either number two or three with straight eaves.

R. Siedenburgh winning the collection of six varieties.

The Garden Clubs made a fine showing, their classes being well filled. The amateur classes also were keenly contested. Prizes for baskets for effect were won by George Hewitt, James Tough, William Shaw and W. H. Maple. The feature of the last day was the table decorations. John Rutherford, gardener to Mrs. Hooker, was first, and George Hewitt, gardener to Mrs. Topping, second. Among those who had trade exhibits were: Mrs. R. Stewart Leckie, Stumpp & Walter Co., J. H. Troy, and Mills & Co.' Mills & Co. exhibited their new Dahlia, Myra Valentine. It is of the decorative type, a golden bronze.

ANDREW KNEUKER, Cor. Secy.

NASSAU CO. HORT. SOCIETY

The monthly meeting of the above society was held in Pembroke Hall on Sept. 12. President James Gladstone occupied the chair. William Framed, J. A. Fichter and John Corciza were elected to active membership; five petitions for active membership were received at this meeting.

Messrs. Woods, Carter and Westlake judged the exhibits and their decisions were as follows: six onions, first, John W. Everett; three sticks of celery, first, John W. Everett.

The Chrysanthemum schedule was read to which many new classes have been added this year.

ARTHUR COOKE, Cor. Secy.

STAMFORD HORT. SOCIETY

The regular mid-monthly meeting of the above society was held Sept. 17, with a good attendance of members.

A fine display of flowers, fruits, and vegetables was seen and appreciated by all who were there. The awards were as follows: Apples, P. Donovan, first prize; Apple and Pears, A. Hay, second prize; Vegetables, A. C. Boon, first prize, Cultural Certificate; Cucumbers, A. Geddes, Cultural Certificate; Dahlias, A. Geddes, first prize; Seedling Dahlias, A. Geddes, Certificate of Merit. The recent Dahlia Show held at Stamford was an event that brought out many fine displays. The Fall Show of the Society will be held in the Horticultural Hall on Nov. 2, 3, at which there will be a splendid lot of classes with special features in the fruit classes for the big prize for Apples given by Mrs. Helen Porter, of Stamford.

A very pleasant meeting then came to a close.

FREDK. WHITEHOUSE, Cor. Secy.

CLEVELAND HORT. SOCIETY

The regular meeting of the above society was held at "Glenallen," the estate of Mrs. F. F. Prentiss (Mr. R. P. Brydon, Supt.), on the evening of Sept. 13. The greenhouses were inspected where the stock was all found to be in excellent condition.

The meeting was called to order in the service building by President J. M. Stevens and the usual routine of business was transacted. Frank Balogh, gardener on Moreland Farm, was proposed for membership. J. C. Reibeling and Carmine Gyssels were elected to membership.

Carl Hagenburger, of Mentor, talked on the coming National Show to be held here March 29-April 5, 1924, and also Mr. Brydon, who mentioned that the N. A. G. medal would be awarded, N. A. G. members to take note.

A resolution was adopted to help make the National Garden week a memorable event in 1924, April 22 to 28.

Two vases of Dahlias were exhibited by George Wyatt, gardener on the Parmelee Farms, Painesville, which were very well grown and received a Cultural Certificate.

A vote of thanks was rendered to Mr. Brydon for his courtesy in entertaining the members.

W. J. BRUCE, Secy.

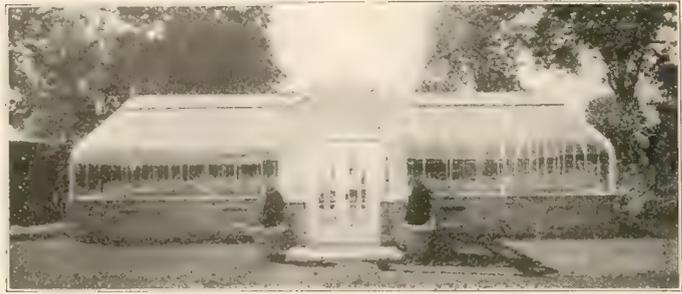

NARRAGANSETT GARDENERS' AND FLORISTS' ASSOCIATION

The members of this association visited some of the leading estates of Newport on Wednesday, Sept. 26, and were the guests of the Newport Horticultural Society.

Among the estates visited was that of E. J. Berwind, where the terraces and sunken gardens with their artistically trimmed hedges, noteworthy among which are the dwarf hedges of Euonymus, are the outstanding features of the gardens. The richness of the green lawns and hedges are broken only by the beautiful beds of red flowered Begonia Erfordii rubro.

The next estate visited was that of Mrs. T. J. Emery. Here the hardy borders with their mass of color are the leading features, and also the massive rock gardens. Everywhere the visitors were surprised by having a tree and its projected horizontal picture unfolded to their view.

The Swiss Farm of Mrs. Curtis James was one of unique surprises for the visitors and showed much originality. The greenhouses here are filled with tender winter flowering plants, and the garden is a beautiful scene.

A Bar Greenhouse Built by Louis B. Tim, Long Branch, N. J.

Lutton V-Bar Quality Greenhouses

Maximum production at minimum cost of maintenance. Scientific, efficient heating system insures even temperature on coldest nights.

Owned by people who can afford the best yet cost is reasonable.

Perfect ventilation extra high headroom, providing space for tall plants on side benches.

Strong, durable, sanitary construction combined with lightness and beauty of appearance.

So easy to take care of—no trouble, no repairs, no worry.

"The Gardeners' Greenhouse"

This type has aptly been applied to the Lutton Patented V-Bar Greenhouse for the reason that their best ideas and particular needs are embodied in its unusual construction. A few exclusive features are its indestructible sanitary type of flat benches with galvanized iron frame, porous tile bottoms and slate retaining sides.

Write or call for further details, photos and evidence of superiority.

ASK A LUTTON OWNER

WM. H. LUTTON COMPANY

260 Kearney Ave.,

Jersey City, N. J.

Begonias which are in their prime and give promise of yielding a wealth of blooms at Christmas. The elaborate blue garden is the outstanding attraction on this estate.

Next on the program was the estate of Mrs. Hugh D. Auchincloss, where everything is done on a large scale. The rose gardens and the extensive rock gardens easily excel, with the greenhouses coming in for their share of notice, for here all kinds of vegetables are in all stages of growth for the coming winter.

The estate of Ex-Gov. R. Livingston Beeckman was a treat to all, for seldom does one see Adiantum Parlyense grown to such a degree of perfection as it is here. Gardenias, too, are also a feature in the flowering plants and again is perfection attained in their culture.

The estate of John Aspergren was the scene of a wonderful display of Dahlias, not

only from a standpoint of new and rare colors but also the general condition of the plants, which were as good if not better than any dahlias in this section of the state.

We wish to thank the Newport Horticultural Society for their hospitality extended to us and particularly do we appreciate the efforts of Mr. Brown and Mr. Urquhart, who cheerfully gave their entire time for our entertainment.

CHESMAN O. CHILDS.

AMERICAN DAHLIA SOCIETY SHOW

While the commercial side of the growing of dahlias was well represented at the annual show of the American Dahlia Society in New York on September 26-29, the interest of the amateur gardener was not so

noticeable, due in all likelihood to the unseasonable weather which has caused much disappointment to dahlia growers this year. Though all the exhibits were not of the usual high standard, taken all in all, the show can be regarded as an excellent one, illustrating the increasing popularity of the dahlia as a garden favorite. The officers of the American Dahlia Society continue quite enthusiastic over its annual shows and a committee was appointed to seek larger and more suitable quarters for 1924.

W. Atlee Burpee Co., of Philadelphia, staged their usually attractive exhibit, featuring their new peony-flowered Fordhook Rose. The collection embraced large cactus, decorative, pompon, and show types. The A. D. S. gold medal was awarded to this trade exhibit for flowers grown by the exhibitor.

Two entries appeared in the class for flowers not necessarily grown by the exhibitor. John Scheepers, Inc., of New York, with the one variety, Jersey's Beauty, made a wonderfully fine display. About one hundred long-stemmed blooms were arranged in several large vases against a background of black velvet, which presented a most artistic effect. Jersey's Beauty, a seedling of Mrs. I. deVer Warner, a pure eosine pink shade, was raised by William H. Waite, of Rumson, N. J., and it has been exhibited at different shows this season with great success.

Stumpp & Walter Co., of New York, were awarded a silver medal for their display, which was arranged in two rows of baskets, filled with long-stemmed flowers, all of which were plainly labeled, so that it was easy for the visitors to read the name cards. A large number of varieties were displayed, including Millionaire, Judge Marean, California Gold, Sulphurea, Lady Betty.

Charles H. Totty Co., of Madison, N. J., staged a large and effective exhibit of dahlias, some of which were immense in size and among which were noted Mephistopheles, Insulinda and Etendard. Gladioli, delphiniums, and the beautiful rose Claudius de Pernet were other notable features of this exhibit.

George L. Stillman, of Westerly, R. I., had a very nicely arranged exhibit of one hundred and fifty varieties. Two new varieties, Head of the Nation, a purple maroon hybrid cactus, and Our Country, a deep purple with a white tip, decorative type, were prominent features.

Henry A. Dreer, of Philadelphia, showed several pleasingly arranged baskets of new varieties in which were included Jean Chayot, a choice flower of the cactus type, burnt orange in color, a new French variety, and Pride of San Francisco, a beautiful, golden pink of the decorative type.

William H. Waite, of Rumson, N. J., showed vases and single specimen blooms of enormous size. Francis Lobdell, Ambassador; Mrs. John T. Scheepers, Jersey's Jewel, Jersey's Gem and Gertrude Dahl were noted.

W. W. Kennedy of Red Bank, N. J., carried off the first prize for one hundred distinct blooms, showing a splendid collection.

As already stated the private growers and amateurs did not come forth as might have been expected. Miss Myra Valentine of New Canaan, Conn. (G. Carver, gardener) won in the class of fifty "shorts." Judge Elkins (E. Griffith, gardener) won in the class of twenty-five blooms and also staged a fine collection of long stemmed flowers in the display class, covering one hundred square feet. W. Atlee Burpee Co.'s silver cup and the Garden Club of America's medal were won by F. R. Waite of Montclair, N. J., who showed some fine flowers in the best general amateur display and also won the most meritorious exhibit class.

SEWICKLEY, PA. DAHLIA SHOW

The third annual dahlia show held under the auspices of the Garden Club of Allegheny Co. and the Sewickley Hort. Society on Sept. 19-21 was a highly successful event, considering that the growers had the elements to contend with practically throughout the entire growing season. There was a good attendance each day at the show.

Mrs. W. B. Snyder (William Thompson, Jr., gardener) won the silver cup for the exhibit of one hundred square feet of dahlias. Mrs. Snyder also won the challenge cup. W. W. Wilock (R. Boxel, gardener) won the American Dahlia Society's medal for fifty blooms not less than six of a type. The award for the largest bloom also went to Mr. Wilock.

Among the other prominent winners were Mrs. E. M. Horne (Manus Curran, gardener), Mrs. H. R. Rea (Alex Davidson, gardener), E. A. Woods (H. Gibson, gardener), H. L. Mason (James Murphy, gardener) Mrs. Alex Laughlin (Henry Goodband, gardener) Col. Schoonmaker (John Carman, gardener), Mrs. B. F. Jones (William Baumgartner, gardener) and Hermann Rapp.

FIBRE FROM THE CAT-TAIL

The ordinary Cat-tail, which grows in marshy places and along streams over wide areas, has hitherto been chiefly admired for the handsome brown spikes from which it gets its name. Its leaves are used too for making rush-bottomed chairs. New uses have been found for it in Germany, born from their needs, and it is now announced that it is a most important source of textile fibres and also of food. This plant, the *Typha latifolia*, gives fibres which are not so fine as those of cotton or the nettle. Neither have they the softness and whiteness of fibres from these two staple plants. For this reason these fibres were employed only as a substitute for jute until about a year ago, but it is now announced that such gratifying progress has been made in improving the process of manufacture that it will probably become of great commercial importance, and is even expected largely to take the place of wool. The yield of fibre from this plant is very high, amounting to about thirty-three per cent, whereas air-dried nettle stalks yield only from six to eight per cent.

It is found also that the root of the *Typha* contains considerable quantities of nutritious material. These roots become felted together in cushions thirty to forty centimeters in thickness, and the roots of the single plants are sometimes as much as twenty meters long and ten centimeters thick. They contain carbo-hydrates in the form of starch and sugar, stored up for the use of the plant in amounts of as much as twenty-five to thirty per cent. They are thus capable of being used to feed cattle and even human beings. *Scientific American*.

KIRSTENBOSCH NATURE RESERVE

In the richness and variety of its flora the Cape Peninsula somewhat resembles California. When the winter rains set in, hillsides and valleys are carpeted with flowers of all descriptions. Many of these flowers are not to be found elsewhere. Every province differs in vegetation, but the Cape Peninsula is especially qualified for a nature reserve on account of the rarity and variety of its floral specimens, and for the beautiful scenery which gives it a fitting background.

It is now 10 years since a gift from a private individual formed the nucleus of what is at present the Kirstenbosch Nature Reserve. Treated at first as a national botanic garden, it was kept exclusively for South African indigenous plants. These were obtained from all parts of the Union, South West Africa, and Rhodesia.

The protea collection is generally considered the most valuable. When in flower the proteas are inexpressibly beautiful. One may see the giant protea, with a bloom as large as a cabbage, its size offset by the wonderful delicacy of its velvety pink petals. It is known commonly as the "Mountain Rose," and grows on the mountain tops. There are many other varieties of protea, not quite so large, but equally beautiful. One lovely specimen is of a creamy-white color, tipped at the edges of the petals with the softest down of black hairs. It is a characteristic of the protea family to have this soft down on their petals, culminating in their tops in a more vivid and contrasting color. The leaves are generally fleshy, and extend right up the stem to the flower.

The succulent plants are a unique part of the Cape flora. In fact, they are so distinctive in South Africa that it has been decided to send a collection of succulent plants to London for the Empire exhibition at Wembley.

Last year the florist department added an extensive area to the already existing Kirstenbosch Gardens, so that in all the National Reserve now covers 1060 acres. The additional or new reserve continues right to the top of the eastern slopes of Table Mountain.

On the slopes of the mountain one may see the famous silver-trees. They grow nowhere else in the world, and are not indigenous to any part of South Africa except the Cape Peninsula. Some of the finest specimens are in the Kirstenbosch Reserve, several feet in circumference. The tree does not grow to a very great age, like the oak, but is at its best in the full vigor of youth. Its graceful shape would lose its beauty if it took on the great massiveness of age. The leaves of the silver-tree are long and narrow, and covered with a fine, silky down, which when lying flat gives the appearance of a silvery film. The down is affected by atmospheric conditions, so that at certain times the tree appears much more silvery than at others. The silvery-gray stems greatly increase the illusion of the tree being made of silver. Besides the silver tree, the ravines and slopes of the mountain contain 40 other species of indigenous trees. There are also ferns and orchids, and on the open spaces many different kinds of heath.

The Kirstenbosch Reserve is very near to a large city. In Natal a large nature reserve has recently been set apart in the Drakensberg Mountains, but it is rather difficult of access to the ordinary tourist and does not possess the variety of scenery of the Kirstenbosch Reserve, where the mountains look down upon the sea. Excellent roads make automobile travel easy and pleasant, and tourists from all over the world come in increasing numbers to enjoy the Cape Peninsula and its beautiful flora.—*The Christian Science Monitor.*

DAHLIA SUGAR

The cultivation of Dahlias has developed so many beautiful varieties, and the flower has been so much improved that it comes with something of a shock to some folks to learn that Dahlias are to be grown on a commercial scale for the sugar to be obtained from their bulbs. They will also be surprised to learn that more Dahlia bulbs can be raised to the acre in California than Sugar Beets. Nor does it cost more to raise them. However, the Dahlia bulb has less of sugar content than the Sugar Beet so it will likely cost more.

The new sugar is one and one-half times as sweet as cane or beet sugar and will hardly be a rival to the other sugars, as it will be more along the medicinal line. In this connection it may be mentioned that sugar was regarded as a medicine or a luxury in Europe up until the time that tea and coffee began to be universally used, and not a necessity, as it is now regarded.

The formula for making the Dahlia sugar was worked out in the laboratories of the University of Southern California, and the head of this department, Dr. Laird Stabler, states that it is now complete. The American people consume more sugar than any nation in the world, the consumption per capita in the last year being nearly a hundred pounds. This is an increase over the previous year.

Perhaps when the Dahlia fields get to growing, they will be allowed to flower, though this is hardly likely, as it will probably appear that it would detract from the amount of sugar stored up in the Dahlia roots.—*Scientific American.*

SOIL CONDITIONS INFLUENCE NIGHT AIR TEMPERATURES

A relation has been shown to exist between the temperature of the soil and the ensuing minimum temperature of the air immediately above. Low night-air temperatures in garden and truck farms may often be prevented by the selection of soil in which there is a sandy component, as sand and sandy loams generally store up more heat during the day than do most other soils and give off more in the night-time by conduction to the air above, thus diminishing the probability of critical temperatures and the formation of damaging frosts. The land in use should be well drained of surplus moisture, as wet soils are invariably cold soils and more susceptible to frost damage. Any soil, whether it be sand, loam, or clay, is warmer when it is clean and free from weeds and unnecessary vegetation.

Frost may form on one side of a street and not on the other, or in one section of a level farm and not in another, for one or more of several reasons, such as difference in soils, slight difference in elevation, in moisture, or in kind and extent of surface covering, or the amount of insulation received. Frost may appear in sections which have wet, cold soils covered with heavy vegetation or uncultivated, while on the same night and under the same meteorological conditions it does not form on other ground close by where the soil is relatively dry, warm and clean.—*U. S. Weather Bureau.*

*Fred Whitehouse,
Superintendent, The
"Uplands"*

A view of the "Uplands" garden by Mrs. Frances S. Holbrook's Estate at "The Uplands," Stamford, Connecticut

The tribute of Fred Whitehouse to Davey Tree Surgery

"Uplands," Strawberry Hill, Stamford, Conn., July 12, 1923.

THE DAVEY TREE EXPERT CO., KENT, OHIO.

Gentlemen:

It is with great pleasure that I commend the work done by The Davey Tree Experts on Mrs. Frances S. Holbrook's Estate.

The trees treated several years ago are now doing splendidly. Mrs. Holbrook has your men visit her place yearly to inspect and attend to any of the trees that need treatment and attention, as there are many beautiful specimens on this Estate.

Your staff of men are courteous, industrious and very efficient at their work.

I would gladly recommend you to anyone requiring the service of Expert Tree Surgeons.

Yours very truly,

FRED WHITEHOUSE,

Superintendent.

To save fine old trees, every gardner and estate superintendent needs highly skilled assistance. Many, like Mr. Whitehouse, protect their trees by Davey Tree Surgery—a science developed by years of patient study and experience. A careful examination of your trees will be made by appointment.

THE DAVEY TREE EXPERT CO., INC., 310 Elm Street, Kent, Ohio,

JERSEY'S BEAUTY—*The Greatest Dahlia Under Cultivation*

A REAL pink Decorative of exquisite shading; a soft pastel, translucent pink of intense richness. Large deep blooms of perfect form on extra long, stiff stems, and of extraordinary keeping qualities. The graceful form of the flower with the long outer petals curving back to stem, is as pleasing as it is artistic. Altogether, a floral creation of lasting charm.

It is important to make reservations now.

Tubers—A limited number, \$25.00 each.
Ready for delivery April 1st and thereafter.

Has Gold Medals, Certificates, First Prizes, and other high honors to its credit. "Jersey's Beauty" scores highest of any Dahlia at the Trial Gardens of the American Dahlia Society, being awarded 91 points for perfection and merit, grown in company with the World's Best Dahlias. "Jersey's Beauty" has succeeded exceedingly well everywhere, including in California.

Plants (guaranteed to arrive safely), \$10.00 each.
Delivery during May or June.

WHY BUGS LEAVE HOME

"Munmar" Newport, R. I., July 9, 1923.
Andrew Wilson, Inc., Springfield, N. J.
Gentlemen: It is with great pleasure that I recommend Wilson's O. K. Plant Spray. I have used it on Boxwood, and it has thoroughly cleansed the latter of Boxmite. I have also found it very satisfactory in the greenhouse as well as in the garden. It is indispensable to the upkeep of the estate.

Yours truly,
H. A. BURGESS
Supt. of Mrs. A. Hamilton Rice's Estate

Gardening Under Glass

"A helpful guide in greenhouse work the year round"

BY F. F. ROCKWELL

This book is both entertaining as well as instructive. It is written in a language so understandable that one needs no special knowledge of horticulture. It is a guide to those of the more experienced gardener. It is a complete manual of operation and arrangement.

No. 11

Things and Thoughts of the Garden

WILLIAM N. CRAIG

NOVEMBER to many is a very sad month as "chill November's surly blasts have made fields and forests bare," but the oaks and some other trees still have high colorings and in the shrubberies there is cheer and brightness in plenty on the many fruiting shrubs. In looking over a large number of these berried plants I have been struck by the lavish display of brilliant fruit on the common barberry, *Berberis vulgaris*, and if asked to name the shrub which in my estimation made the finest display I would unhesitatingly plump for this old, very common, and in many states, tabooed plant. One particularly brilliant effect was produced by planting quantities of this barberry with a background of tall cedars (*Juniperus virginiana*). *B. Sieboldii* is another tall growing variety which to the uninitiated would be mistaken easily for *B. vulgaris*; its fruit is very handsome and persists until Spring, and its foliage, when unfolding is of a purplish color and assumes a brilliant red color in Fall. The Japanese barberry so heavily used for hedging purposes, when planted out so that it can have ample room to spread, makes a striking effect. One of the original plants of this very popular shrub grew until recently along the Arborway in the Boston park system near the Forest Hills entrance to Arnold Arboretum, and was the grandest specimen I have ever seen, being over 15 feet across and of perfect form. It seemed something of a crime to remove it, but autoists claimed that it obstructed their vision, hence its removal. There are many other barberries including handsome new varieties from China, some of which are evergreen even as far north as Boston in an extraordinary Winter and others are notable for their dark, glossy foliage or brilliant fruits. *B. Koreana* has very handsome fruits; *B. verruculosa* has violet black fruits and has withstood a temperature of 20 below zero. *B. Gagnepainii* also carries blackish colored fruits and proves an evergreen in the more balmy states. The very handsome *B. Sargentiana* carries black fruit and its foliage is particularly handsome. It is not in trimmed hedges that we can secure the full beauty of the *Berberis*; in their mutilated condition they can fruit but moderately, and bear mute testimony to what a fine showing they would make at this season if allowed to grow naturally.

* * *

Speaking of dark colored fruits, there is no shrub which makes a finer fruit display now than the common privet, *Ligustrum vulgaris*, the fruits of which are produced in great profusion and persist right through the

Winter. A great many people plant hedges of the Japanese privet (*Ligustrum ibota*) or the California privet (*Ligustrum ovalifolium*) which later is a much more tender variety, and ignore *L. vulgare* and its great value as a shrubby plant both for its bloom and its fruit. Of the shrubs producing dark fruits, one of the most striking is unquestionably *Symplocos paniculata* the bright blue berries of which instantly attract attention. At this time the large bunches of bright red fruits carried on the high bush cranberry (*Viburnum opulus*) excites our admiration, and several of the other *Viburnums* are heavily fruited. By no means to be despised are the masses of *Symphoricarpus racemosus*, the common Indian currant, whose purplish red berries remain fresh all Winter, while the large oval pure white fruit on *S. racemosus*, the "Snowberry," are already becoming discolored, although many remain plump and white until Christmas.

* * *

How handsome now also is the *Euonymus*! *E. Europæus*, commonly called the "Burning Bush," makes a truly glorious showing with its wealth of brilliant fruits which are really seed pods, and almost smother the plants. The "cork barked" *Euonymus* still retains some of its brilliant leaves in early November and its richly colored fruits give the shrub a firelike appearance. The evergreen, *E. radicans vegetus*, also makes a wonderful fruit display now where it has not been subjected to shearing and is in a strong light. The other forms of *E. radicans*, like *Carrieri*, fruit much more sparsely than *vegetus*.

* * *

Some of the *Cotoneasters* have dropped their fruits but on *C. horizontalis* the rich red fruit will remain all Winter. Some of the *Cornus* family are now very attractive, and if to these are added the many *Cratægus* or hawthorns, the ornamental crab apples, the Japanese quince, *Cydonia japonica*, it can readily be seen what brilliant and varied fruiting effects may be had by making judicious plantings. I should have included the winterberry, *Ilex verticillata*, whose rich orange fruit is always in great demand at the holidays. And what is more beautiful than the common woodbine, *Ampelopsis quinquefolia*, hanging over a wall loaded with its bunches of rich blue fruits? And the various rose species fruit abundantly and in some cases remain bright until Spring approaches. This is by no means a full list of fruiting plants which give color effects, when foliage is scanty; but it may encourage some who

are lacking in plants which cheer as the season ends, and induce them to give more attention to them.

* * *

There are, and will no doubt continue to be, differences of opinion as to whether Fall or Spring planting of hardy roses gives the best results. At one time I was very much prejudiced in favor of Spring, but plantings made in the Fall of recent years have convinced me that Fall planting gives far more satisfaction. From Spring plantings, I am satisfied that in New England from one-fourth to one-third of the plants set out either die or merely exist. This is not strange when it is remembered that nearly all the Spring planted stock has been carried over Winter in storage houses and is, in too many cases, badly dried up and shrivelled. It is hardly surprising that, unless in the hands of those who will give it the best attention, a large proportion will die. Nurserymen are swamped with orders in Spring and it is often very late when orders are filled. It is quite otherwise in the Fall when nurseries are rarely overtaxed to keep abreast of orders and when all roses are dug from the field as wanted and received by the buyer in a plump, fresh condition.

In my experience, the last half of October and the first half of November is the ideal time to plant hardy roses in New England and no doubt the planting season could be very well extended further south. Given well prepared ground, careful planting, which means spreading out the roots well and firming the soil thoroughly about them and also deep planting, and before the ground freezes up-hilling each plant with soil and later furnishing a mulch of leaves, meadow hay, straw, or litter, there will be a far smaller percentage of deaths from Fall than Spring planting. There is simply no comparison in the growth of the two plantings. I have taken up plants when hilling them up and have been pleased to see the quantities of white fibrous roots the Fall planted stock, was sending out. I have no doubt, however, that most of the readers of the GARDENERS' CHRONICLE OF AMERICA will continue to depend on Spring planting of hardy roses. If so, I should counsel them to buy their plants even thus late and bury them over Winter on a well drained piece of ground, so that they can be planted just as soon as the ground is open in Spring. Try this plan, and buy a few others in Spring and if you will carefully compare results you will be ready to both buy and plant your roses in the Fall of another year. Hybrid teas can be just as successfully planted in Fall as hybrid perpetuals, polyanthas, climbers and rugosas.

* * *

There has been an unusually good demand for all hardy bulbs this season. The Breeder and Darwin tulips are being called for more than ever and the fact that the powers that be in Washington have temporarily relented and permitted the importation of snowdrops, scillas, chionodoxas, and a few other bulbs which have been debarred for a year or two and which no one seems to be able to produce here, is good news to many garden lovers. Most of these bulbs look best when naturalized in grass land where the grass will not be cut until the foliage on the bulbs has matured, and in planting them they should be scattered by the hand and planted where they drop in order to look natural. The short trumpet Narcissi are much better for naturalizing than the big trumpet sorts. Of the latter, such old sorts as Emperor, Empress, and Princes, look well and persist from year to year, while such kinds as Henry Irving, Golden Spur, and Glory of Leiden prove unreliable. The short trumpet sorts look much more pleasing in a naturalized state than the sorts just named. Of the older sorts which last well from year to year I would select Poeticus, Leedsii, Mrs. Langtry, and Barri conspicuum which are hard to beat. Not many realize how

splendidly the Darwins succeed in grass, and they do not run out as quickly as might be imagined. A tulip which succeeds especially well in grass is the brilliant Gesneriana spathulata; perhaps too high a color to suit many but suitably located it will be found hard to beat. One of the very best bulbs in grass is Scilla (Puschkinia libanotica) which increases very satisfactorily, and should be more largely planted. Fritillaria meleagris alba is another bulb which should be more planted in this way.

So far I have been unable to learn of any American grower who has succeeded in making a success of the field culture of scillas, chionodoxas, galanthus, fritillarias and others of the "dangerous" bulbs which have been debarred for several years, but are now temporarily procurable. Seeing the keen delight amateur gardeners obtain from the culture in even a very small way of these lovely little early flowering bulbs and the fact that their commercial culture seems to be too much for our hardy bulb specialists, I hope the Federal Horticultural Board will change its attitude and permit these simple, early flowering and popular bulbs to come in unrestricted hereafter. They are our first harbingers of Spring, and we can ill afford to dispense with them.

* * *

A friend who is superintendent of a large private estate in New England, and who has just returned from an extended tour of Great Britain, finds that the great war in no wise decreased the love of horticulture in the people of that island. He attended some of the largest flower shows, including Shrewsbury, Glasgow, London and Liverpool and the quantity and quality of the exhibits as well as the tremendous crowds of garden lovers who attended them amazed him. This gentleman says that the Glasgow show was the greatest of all, even surpassing Shrewsbury, which latter had 100,000 paid admissions on the second day. When we stop and reflect that this attendance probably equals, even if it does not exceed the gross attendance at all our Spring exhibitions or all our Fall shows combined, it is easy to see that the flame of horticultural enthusiasm is undimmed over there as yet. Another statement made by my friend was that when it comes to staging roses, carnations, sweet peas, phloxes, groups of herbaceous plants, and vegetables effectively, we know practically nothing in America. In mass production we stand high, but when it comes to arrangement we are simply not in the same class as our cousins across the ocean. It is good to have a little conceit knocked out occasionally, and I wonder if we had suffered as they have, and still are suffering, if pessimism and not optimism would not prevail in horticultural circles here.

* * *

Albert C. Burrage, president of the Massachusetts Horticultural Society as well as of the American Orchid Society, visited 17 leading orchid establishments on the European continent recently while visiting there. I asked him what impressed him most, and he said the remarkable cleanliness and general thrift of the bulk of the establishments visited and the tremendous culture of Cymbidiums. At one big commercial plant, house after house of these plants was seen, including almost numberless quantities of seedlings of the very best crosses. The owner stated that with a return to more normal conditions in Europe they had faith that there would be an enormous demand for these plants which could be grown fairly cool, flowered freely, and produced flowers of great lasting qualities. It is evident, therefore, that Cymbidiums are destined to be one of the great orchids of the near future, and the producing of species which

(Continued on page 273)

In the Garden and in the Greenhouse

GEORGE F. STEWART

IN THE GARDEN

A GARDEN, even in such a chilly period of the year as late November and early December, has more or less attraction for mankind. I have often wondered why we are seemingly so closely wedded to a garden, but yet, why should any of us marvel, knowing that the Creator planted a garden and that he placed man in it. Furthermore, from the wording in the original language, and from some little study I have made of the roots of the words used, I am persuaded that at least the body of Adam was Yotsar, translated formed, from the soil of the Garden of Eden. Man's body was not a direct creation like his soul and spirit, but was framed or formed from material then existing, the dust of the ground. The word Aphar, translated dust, is a refined sort of word and according to some lexicographers might be translated clean soil, or in other words that kind of garden loam that the gardener delights in when planting time comes, and does not hesitate to handle with bare hands freely. I venture to say here, that our scientific friends, before they swallow the evolutionary theory as an absolute certainty, would find it quite an interesting study to examine the various renderings, given in lexicons, of roots of the words used in the account of the creation of man, as given in Genesis. If what I have hinted at here has any foundation of truth in it, and I believe it has, is it any wonder that we all love a garden, seeing that our bodies are a part of the material that plants are planted in? Some of my readers will be accusing me of being like the two nations described by Carlyle in his Rectorial address to the students and friends of Edinburgh University when he said, "The two finest nations in the world—the English and the American—are going all the way into *wind and tongue*," so let us get into our garden for practical work.

The growing season is now practically over. Frost has laid its icy hand on nearly all outdoor flowering plants. Here and there, in some sheltered, sunny nook, some flowers will be struggling to raise their faces to the sun, but for all practical purposes outdoor flowers are gone. As long as the soil is free from hard frost, put all bulbs that are to be planted outdoors into the ground as quickly as possible. As a rule, unless the herbaceous borders have been given a general overhauling, digging will be deferred until Spring. However, after the tops of the plants have been cut and laid aside, until the ground freezes over quite hard, a good close hoeing may be given, leveling in any depressions that may have formed during the Summer, and at the same time removing any weeds that may have been overlooked.

Chrysanthemum plants that have a place in the borders for Fall display should be lifted and stored in a cold frame during the Winter. Some varieties are perfectly hardy, others are not, so it is advisable to take no chances with them. Allow the ground to become frozen quite hard before any covering is done, and then only enough to keep the soil from thawing out until Spring.

Some gardeners complain of having difficulty in bringing *Anemone japonica* through the winter. It should be planted in well drained soil and well covered with at least a foot of leaves, or some such loose litter. Where this has been done it winters well. The greatest trouble we find with this lovely plant, as I mentioned in last month's notes, is in having it cut down with early frost before it is half through its flowering period. *Incarvillea*

Delvayii, we also find, needs Winter treatment similar to *Anemone japonica*.

Roots of *Dicentra spectabilis* may be lifted and stored in some place where they can be reached during Winter. They force well and are a lovely color when in flower. The dwarf Larkspur, which also does well, forced in early Spring, can now be had in various shades of blue and white. There is no doubt but that what is called "Blue Butterfly," and other names, is only a form of *Delphinium Chinense*. It is deceiving to place such things among annuals in catalogs when they are really perennials and may be used as herbaceous plants.

It is well to erect windbreaks in front of *Rhododendrons*, if they are planted in exposed positions. Strong sunshine is also bad for them. In this latitude they grow better when planted in a position where natural plantings of trees shelter them from the northwest, and enough on the south and east to break the strong rays of the sun, especially toward Spring. It is well also to have them thoroughly watered before the ground freezes over, especially after such a dry season as we have just experienced in and around Boston. When raking leaves, work a good covering over the *Rhododendron* bed. It would seem from experience that this is the natural food for them, but we believe it can be also overdone. We do not believe in heaping the leaves up the stems as we have seen done.

All evergreens should be well watered before the ground freezes over if they are expected to winter well.

There is no doubt that the best protection for roses, especially the hybrid tea forms, is loam. However, very few of us nowadays can afford the time to devote to such an elaborate covering as is made by one or two of our neighbors. We can only hurriedly draw the loam up around the plant and fill in with leaves or straw manure. The result of this is that our plants are much more dwarf than those that have been laid over and completely covered with loam. Standard Roses are very effective in certain positions, but in our climate, unless they are laid over and well protected with loam during the Winter, they will not prove much of a success.

Specimen trees, whose habits make them liable to be weighted down with snow, ought to be supported and tied in such a manner as will not cause them to lose their shape.

Boxwood is another plant that often suffers during Winter. Some use a covering of straw, others use a screen of burlap on the sunny side, but in the latitude of Boston we have seen the plants damaged either way, and those that were left without protection come through as little damaged as those that were protected. There are so many factors which enter into the cause of Winter killing that it is rather hard to form a set opinion. For instance, we have seen with the native Juniper, one which came through all right, and a plant alongside which was killed outright. They were only a few feet apart and growing apparently under identical conditions.

There is still plenty of work to be done among the vegetables. Cabbages will have to be stored; they keep well outdoors buried head down and covered with leaves or other litter. A few heavy branches laid over them will keep the wind from blowing the covering off.

Celery is the real standby in Winter and it should be protected before heavy frost sets in. In a well drained piece of land it keeps in the trench that it is grown in, if covered over to a good depth with straw or salt hay. Of

course, it is easier to reach in a frost-proof cellar, but if stored thus, in sand, the roots must be kept fairly moist and air admitted whenever the weather is favorable to do so.

Onions may be cleaned as soon as they are thoroughly ripened and spread out thinly on airy shelves; the building in which they are wintered should just be kept above freezing point.

Brussels sprouts are improved in flavor by a little touch of frost but before they become too wilted with freezing should be protected. Stored cauliflowers need every attention as regards airing, if they are expected to keep well.

There is still time to lift roots of parsley and pot them, or plant them out on a bench; however, seeds should be sown right away, if a supply is to be kept up, as roots lifted from outdoors soon run to seed.

Do not let the time slip by before the French Globe Artichokes are well protected.

Parsnips winter best in the ground where they are grown. We remember only one Winter in thirty-three years when they were injured by frost, and that year we had very little snow; the glass went twenty-four below zero, which is a very unusual occurrence in this locality. A part of the planting may be covered with leaves, or other litter, so that a Winter supply may be obtainable when the ground is frozen.

Do not cover the Strawberry plants until the ground freezes quite hard, and on no account put on a heavy covering. They winter far better if they remain in a frozen condition, and they are like many other plants in that good drainage is essential. We have had very fine success by having a good width between the rows, and before the ground freezes hard by running a deep furrow on each side of the rows, keeping about nine inches away from the plants.

Lettuce in frames needs plenty of air; the heads ought to be quite well formed before it is necessary to place the sashes over them.

Tomatoes that have been grown in pots for Fall use should be well covered with green fruit. A sunny position in a greenhouse, with a night temperature close to sixty degrees, is necessary to ripen them.

Keep collecting good horse manure for a successional crop of mushrooms. The earlier beds will now be bearing, and watch carefully that they do not get too dry. Water with rain water if it can be obtained, taking care that the chill is taken out of it. As the bed shows signs of exhaustion, a large teaspoonful of nitrate of soda may be added to every three gallons of water used.

Give the pot Strawberries that are to be forced about ten degrees of frost before storing them in a cold frame, or if frame space is not available cover them over with straw in some convenient corner where it is easy to get at them when the time arrives for forcing a batch.

In December the outdoor fruit trees may be sprayed for scale and other diseases that affect the wood; also, if any tree is going too much to wood and not bearing, tunnel under it and root prune it. Any root that is inclined to run straight down into the soil cut back quite hard.

IN THE GREENHOUSE

The greenhouse will now claim quite a good deal of time and attention, as any neglect during the dull months is sure to be felt later on. Nothing should now be over-watered, rather, keep the plants on the dry side until the sun begins to get stronger. On all mild days air freely, and if at all possible, use a little extra fire heat rather than neglect this very important operation. A weak, soft growth will be the result if the houses are kept closed to save a little extra fuel. I have been watching oil heating

quite closely during the past year, and, from what I have learned from close observation, it is away ahead of coal as a fuel. I am not referring to crude oil, but to one of the more refined grades. It practically takes care of itself when properly equipped and so far is more economical. How long this saving will continue I suppose will depend upon demand and monopoly.

The Chrysanthemum by the last half of November will be on the wane, and no time should be lost to clear the roots off the bench so that the space may be utilized for a successional crop. Be sure and save enough stock for next year. Each variety may be set close together in a cool house. We use a cold frame but, of course, if early cuttings are wanted for specimen blooms next year, that would be out of the question, as some varieties are slow at throwing up basal growths, and it is necessary to keep them a little more comfortable than in a frame. Don't cut the stems too low. Dust the crowns with flowers of sulphur and powdered charcoal. As the blooms are cut, keep filling in the space gradually with Antirrhinums, Dimorphotheca, Lupins, Didiscus, Stocks, and any other annuals that will give variety for cut flowers later on.

If the Camellias have at all done well they will now be covered with buds, in fact, a little thinning out would be helpful if larger flowers are desired. During the dull, short days watering must be done more carefully, as over-watering is harmful to the roots at this season. Any plants that need a shift I believe should be shifted at this season, as I find that the root action of the Camellias is about as dormant at this part of the year as at any other period and less injury to the points of roots is liable to happen in the potting operation. Be sure and not over-pot these plants, and use a good fibery upland loam, preferably a little acid. A good fibery peat will give quicker growth but I do not think they set buds quite so freely as in loam.

Begonias of the Lorraine type will now be well advanced to the flowering stage. See that they are properly supported with light stakes. We have found that B. Cincinnati, Melior and Mrs. Peterson are better keepers than the original Lorraine, although they do not attain to such large specimens in the same length of time from a leaf cutting. The Cincinnati raised ones may be had over quite a long period if kept in a cool, airy house after they have set their flower buds. There is no doubt that the Socotrana tuberous rooted hybrids are the finest Begonias we now have in cultivation. There is quite a pleasing range of colors among them, and for a private greenhouse they are among the choicest of plants. A good house is necessary to grow them in and a temperature around 65 degrees should be maintained while they are growing. They also need to be kept thoroughly clean, as regards insects. Leaf cuttings of Begonias may be potted along as soon as they throw up a shoot from the base.

Calla lilies will now require attention regarding food for they are heavy rooters. We grow ours in nine-inch pots and find that occasionally a handful of bone meal scattered on the surface of each pot speedily disappears, the roots absorbing it very quickly. We also water with manure water weekly. They like to be kept moist at the roots and syringed under the leaves on bright mornings.

Cinerarias and Schizanthus must not get root bound until the desired size of pot is attained, which for large specimens is generally about a nine or ten-inch pot. A night temperature from forty to forty-five degrees is high enough, and during the day a rise of about fifteen degrees. Keep them in full sunshine until about March the first. We generally pinch the heart out of the Cinerarias once, and Schizanthus we stop four times before allowing them to run to flower.

Cyclamens for Christmas need to be kept in a night temperature around fifty-five degrees to have them in fairly good flower for that season. For Spring use it is necessary to have a batch grown under the cool method and to remove all flower buds until after the turn of the year.

Keep the plants of *Erlangea tomentosa* in a shady position, as the flowers bleach out and lose that lovely lavender shade which all admire.

Many tropical plants, such as *Allocacias*, *Marantas*, and plants of that nature, should be kept on the dry side for the next month or two. If this rule is followed, they start with more vigor in Spring. *Ardisia crenulata* is a handsome berried plant for Christmas, though they are slow growers, requiring about three years from seed to form a desirable plant. They are tropical and need a much higher temperature than *Solanums*. They are not so free of insect pests, being very subject to scale.

The early *Calanthes* are well advanced towards flowering. See to it that they remain moderately moist until they have finished this stage.

Cypripediums should be kept about 50 to 55 degrees at night, that is, the cooler growing varieties, such as the old standby, *insigne*. *Cypripedium insigne sanderae*, *spicerianum*, *caudatum*, etc., require a little warmer temperature. They all need to be more carefully watered at this time of the year.

Cymbidiums do best where grown cooler than was formerly believed; they are strong rooters when thriving well and may be fed liberally when growing.

Miltonia vexillaria will now be pushing up its growths. However, careful watering is necessary until they begin to root freely from the new growths. Spray them on bright mornings occasionally with some safe insecticide to prevent thrips from getting a foothold.

Odontoglossums are in different stages of growth. They stand all the light possible for some time, and like plenty of moisture in the atmosphere. Look out for slugs, crickets and cockroaches. Cotton wool is not a sure remedy for protecting the flower stems; it is better to have plenty of lettuce leaves scattered around, or any other of the usual traps that capture these pernicious pests.

Cattleya Percivaliana and other hybrids belonging to this family will have finished their growth and should be kept well up to the glass until they begin to open their flowers.

Grapes that have shed their leaves may be pruned. It is better to do it now, as they are not so likely to bleed when they are started into growth. All indoor grown fruit plants keep cool and free from insects at this season.

HIBISCUS

FLORUM AMATOR

THERE are twenty-eight species of *Hibiscus* (Rose Mallow), some of which are herbaceous plants, other shrubs, and some, which grow in the tropics, small trees.

Most of these species are grown for their handsome, hollyhock-shaped flowers, and among the most beautiful of them all are the Meehan Mallow Marvels, hybrid varieties originating with Thos. Meehan & Sons, and the *Hibiscus moschuetos* hybrids (Giant-flowering Marsh Mallows), originating with Bobbink & Atkins.

It is not, perhaps, well known that some species of *Hibiscus* are among our economic plants; the long ribbed pods of *Hibiscus esculentus*, whose seeds are sold under the name of Gumbo and Okra, are used in cookery; *Hibiscus cannabinus*, widely grown in the old world, furnishes a coarse fibre which is known as "Bimlipitam jute"; *Hibiscus Sabdariffa* (Jamaica Sorrel Roselle), is now grown considerably in Southern California, and Southern

Florida for the same purpose for which it has been long grown in the old world tropics; namely, its fleshy calyxes, which when cooked make a delicious cranberry-flavored jelly or sauce, and whose juice when extracted makes a cooling acid drink; *Hibiscus elatus* (Mountain Mahoe), and *Hibiscus tiliaceus*, West India trees, yield the Cuba bast used in tying cigars, and other goods; *Hibiscus Rosasinensis* (Chinese *Hibiscus*) flowers are reported to be used in some parts of the world for dyeing hair, and also for blacking shoes, hence its common name "Shoeblack plant."

The best known of the cultivated *Hibisci*, which are grown for their flowers are *Hibiscus syriacus* (Rose of Sharon), mentioned in the "Songs of Solomon," and of the wild species, *Hibiscus Moscheutos* (Swamp Rose Mallow), which grows freely in the marshes along the coast from Massachusetts to Florida, whose handsome, large, showy, rose-colored flowers appear in such glorious abundance in August and September, and which if grown in upland soil will give almost as satisfactory results as when growing in its native marsh.

THINGS AND THOUGHTS OF THE GARDEN

(Continued from page 270)

will in time span the year may easily make them serious rivals of the *Cattleya* in popularity in America. A friend who only a few weeks ago inspected the noted collection of Sir George Holford at Westonbirt, Tetbury, England, from whence have come many of our finest hybrid *Cymbidiums*, and where 10 men are constantly employed in this famed amateur collection, says that several houses there contained nothing but *Cymbidiums*, and that they were in superb health. The same was noted at other orchid collections. Hence we can see that orchids are still popular abroad and *Cymbidiums* forging rapidly to the front.

* * *

A reader of the *CHRONICLE* in Pennsylvania writes to ask if it is advisable to transplant evergreens of a considerable size in November or December if the ground remains open. The only really safe way to move plants so late in the year is with frozen balls, and this may be very successfully done with not only evergreens but deciduous trees and shrubs as well as apples and other fruit trees. This is a method of removal very popular in states where frost is of sufficient severity and continuity to freeze the balls solid, and removal is best done when there is some snow on the ground so that the heavy balls can be more easily hauled to a new location. Holes of ample size should be prepared now, and trees to be removed dug around, and the balls undermined so that they can readily be removed when severe weather arrives. After removal, straw or litter should be packed around the balls until planting time arrives in Spring. This is the only safe way to move evergreens late in the year.

Quercus conferta, sometimes called *Q. panonica* and the Hungarian Oak, is unusual among Oaks in the clear canary yellow color of its ripening leaves. This is the handsomest of the European Oaks which has been tried in the Arboretum in which it has grown rapidly and promises to become a large and valuable tree, distinct in its large, thick, lustrous, deeply lobed leaves. It is a common forest tree on low mountain slopes and hills in southeastern Europe where it is widely distributed and grows sometimes to a height of a hundred feet and forms a trunk from three to four feet in diameter. The Hungarian Oak is unfortunately still a rare tree in the United States—*Arnold Arboretum Bulletin*.

Notes From An Old Country Garden

ARTHUR T. JOHNSON, F. R. H. S.

ONE of the most trustworthy little plants in giving us masses of color as we pass into Winter is *Polygonum vacinifolium*, which in almost any damp, open spot in woodland or rocky crevices makes hummocks of rosy-pink flowers that are very attractive and last several weeks. Though a Himalayan this is quite hardy anywhere with us, as is its "big brother" from Bokhara, *P. baldschuanicum*. This latter is also a late bloomer and is not only valuable on that account but its extraordinary vigor as a climber has earned for it a great reputation. The Russian Vine, as it is sometimes called, will often make 20 feet of growth in a single season, thus soon adorning a pergola, wall, or old tree with its abundant pale green foliage and fleecy panicles of pinky-white flowers. It enjoys a rich, loamy soil with full exposure and, given the right conditions, there are few climbing plants that will so quickly cover its support as this one.

Of the ornamental currants and gooseberries in cultivation here, mostly of American origin, a good word must be said at this season for *Ribes aureum*, the Buffalo Currant. This, despite anything it may lack as a flowering shrub, makes the fullest amends by assuming a most brilliant color before the leaf fall—an intense crimson scarlet. Nor is it to be despised at blossoming time, for its comparatively large golden yellow blooms are unusual and pleasantly fragrant. We also grow a variety of this called *aurantiacum* whose inflorescences are a bronzy-orange tint.

The best of the whole genus *Ribes*, however, is undoubtedly the old Flowering Currant which was discovered in western North America by Menzies in 1793 and sent over by Douglas in 1826. Though one of the commonest it is still regarded among the choicest of our early-flowering shrubs. There are many good varieties of this fine old currant but it is questionable whether they are much superior to the type. Of these the white one (*albidum*) and the almost blood-red form (*splendens*) are perhaps the most noteworthy. We grew the above in our woodland garden under thin deciduous trees, and, in a sunnier, warmer place, the beautiful *R. speciosum* of California, with its drooping, fuchsia-like flowers, is given a home.

The various members of the *Pieris* (*Andromeda*) group are interesting at this time of year for they are now putting forth their elegant sprays of buds which will break into flower in early Spring. The most striking of these is undoubtedly *P. formosa*, a shrub of some 8 feet, with large leaves like a rhododendron and wonderful racemes of urn-shaped flowers, like magnified Lily-of-the-Valley. This splendid subject, which comes from the Himalayas, is, unfortunately, not quite hardy, but it will, nevertheless, put up with what are to us fairly severe Winters. The pink-flowered *P. japonica*, a very lovely species, is more sturdy, but even it is liable to get its flowers nipped by Spring frosts.

The hardiest of the above genus commonly grown with us is undoubtedly *P. floribunda* which came to us from the southeastern States of America in 1800, and this can always be depended on as an every-year bloomer. The dark green foliage and terminal sprays of pure white blossoms of this species are very effective, but the latter, as is the case with those of most others, should be seen indoors as cut flowers to be appreciated at their full value. *P. nitida*, also a native of the Southeastern States, is another species of about the same stature (6 feet) as *floribunda* but it is too tender for most places with us, hence

its comparative rarity here. Then there is *P. mariana* of the Eastern United States. This, unlike the rest of the genus, is a deciduous shrub and one of considerable merit. But though long known to a few gardens it has never become really popular with us. This is difficult to explain, for *P. mariana* would seem to be absolutely hardy since it is, or was, largely grown at the Arnold Arboretum, Boston, Mass., and it is a late bloomer, not opening its pink-tinted, white flowers until June.

That delightful little evergreen shrublet from the lofty mountains of Central Europe, *Polygala chamaebuxus*, can always be depended on to produce a good crop of bloom in the Fall as well as in Spring. We grow it in cool, shady places in the woodland and rockgarden where it makes cheerful carpets of dark, glossy-green, box-like leaves, the plant varying in stature from 3 to 9 inches. The pea-shaped flowers in the typical species have creamy white "wings" and a lemon-yellow "keel." But the variety, *purpurea* (*grandiflora*), is not only more robust and larger in all its parts, but its blossoms have wing-petals of bright rosy-lilac, the "keel" being orange-yellow, often shaded with a pink flush. This charming little woodlander is quite hardy and thrives in any well-drained loam, vegetable soil, or sandy peat. It has a preference for a cool root-run and in its native home flourishes on calcareous formations.

The Chinese Leadwort (*Plumbago larpentæ*) is another dwarf, sub-shrubby plant that is a regular yearly bloomer from September to Winter. This plant enjoys a warm corner of the rockgarden where the soil is light and where there are stones under which it can send its wiry roots. In such conditions it has lived in this garden for years, on one occasion enduring as much as 27 degs. F. of frost, and every Fall it crowns its 8-inch growths with a cluster of flowers, each nearly as large as a 5-cent piece, and of a most vivid cobalt-blue. Then, as the blossoming season passes, the foliage assumes brilliant shades of crimson and orange. This plant is now botanically known as *Ceratostigma plumbaginoides* and there is a bush form, *C. Wilmotteæ*, which grows to a branching shrub of about 2 feet.

Enjoying a similar kind of root hold and situation as the Leadwort, and not unlike the latter in habit, is the Californian Fuchsia (*Zauschneria californica*). This beautiful plant also helps to give color to our autumnal garden, its bright crimson-scarlet flowers and gray-green foliage being very attractive. Those readers who know the flora of California will not need reminding that in its native land *Z. californica* grows under very diverse conditions and that it varies very considerably in habit, foliage and flower. The form which we in Britain usually try to obtain is an early-flowerer (July onwards) with silky, pale green leafage and blossoms of an intense scarlet. Like the Leadwort, *Z. californica* may be cut to the ground at the end of the season which enables one to give it protection without difficulty where this seems desirable.

The Sweet Gums (*Liquidambar*) are well worth a place in any garden where they can be given sufficient room, for the foliage is extremely brilliant at this season. The most popular species over here is *L. styraciflua* from the eastern United States. This assumes such vivid tints that it is frequently taken to be a maple. The shape of the leaves is also much like that of a maple and a well-grown tree is an object of great beauty.

Another tree of much smaller stature which is deserving

(Continued on page 281)

Garden Design

PERCY S. CANE in The Garden

NEARLY all new grounds, even though quite small in extent, are composed of separate gardens, each having its own particular character, and it is in this subdivision and the proper contrast and relation of the different parts that much of the art of garden-making consists. Terraces, lawns, rose gardens, herbaceous borders, and rock and wild gardens must all be correctly proportioned to the total area of the site.

As well as being of suitable size, gardens should be well placed, that is to say, each particular garden should have the proper aspect and be in the best place for that particular garden. Rose gardens should be sheltered from the north and east and yet have a fairly open aspect. Neither the rose garden nor the tennis courts should be too far from the house.

Much has been written about the respective merits of formal and informal (or "landscape") gardens. Generally, gardens will be less formal in treatment as they are farther from the house, although it will often surprise and please to come unexpectedly upon some small formal garden set amid the more natural parts of the grounds. Gardens of shrubs and lawns, and so-called wild gardens may, if properly planned, be some of the most beautiful and attractive of all.

Let us start from the house and consider planting and the nature of it for the different gardens. Not too far away one should have color, color for the greater part of the year and a lot of it, and here let me say that if one's gardens are set in woods or trees so that one has backgrounds of green, one cannot well have too much color, but if the surroundings are walls, one needs to be careful.

Near the house there must be finished planting with nothing untidy about it. Flowers differ in quality, and near the house one must feel no jarring note between the tastefully decorated interior, and gardens that may often here be something in the nature of outdoor rooms.

For the permanent planting use such plants as Delphiniums (blue Delphiniums may often be used where blue Lupins would seem too coarse), Lilliums, perhaps Tree Lupins, the various Artemisias (Southernwoods), Lavender, Mimulus, some perennial Asters, Campanulas, Scabious, Pentstemons and numbers of other plants.

The plants which constitute the permanent planting should be skilfully grouped to form a setting for the bedding plants and biennials that will be used for their continuity and freedom of flowering, and for the added touch of richness they will impart. In the Autumn one may plant great masses of Darwin Tulips midway or rather back in the border, so that lower plants in front may partly hide their stems and act as a foil to their lovely colors. As well as Tulips, one could have Narcissi, but this family is really more suitable for the more natural parts of the gardens.

Numbers of Hyacinths can be planted in front to grow close to the paving or turf, always in masses of one sort by itself, and Wallflowers, but some of these are of cruder coloring and must be carefully placed. Violas can be treated as permanent residents and left undisturbed until they become weak and straggly and need replacing, and they will flower so early as to be in bloom with the Tulips, that is, if they are planted soon enough. Double white Arabis, Myosotis and Aubrietias in their colors that seem to tone with everything will also be planted for early Spring effects.

The fresh delicate greens of the permanent masses of Delphiniums and other plants will, all the time that they

are growing be the best possible background for the bulbs and other early flowers, and after these have finished there are a host of things to choose from for the Summer. Tree Fuchsias are always useful, they need little care during the Winter—to keep them secure from frost is enough—and they should be grown into as large plants as possible. Begonias (both tuberous and fibrous rooted), Heliotropes, Carnations, Marguerites, Zonal and Ivy-leaved Pelargoniums ("Geraniums"), almost all of the often despised bedding plants can be used here with the best results. Only remember always that they are to be grouped and never arranged as formal bedding, and grouped with due regard to the scheme of planting as a whole. November may seem an unsuitable time to talk of Summer bedding, but it is easy now to visualize results for future seasons.

To turn to more permanent planting—the planning of which is as interesting as it is hoped the results will later on be beautiful—so far as herbaceous plants are concerned it is well first to decide the height and habit of growth that is required to obtain the effect desired, and carefully to consider the color scheme as a whole before actually selecting the plants to be used.

For reds one should be careful in the choice of plants; some are good natured enough to tone with anything, but many reds are inclined to be crude unless carefully placed. Blues are always welcome, and go with nearly every other color except perhaps some reds and browns. Browns and golds and yellows and bronzes may be grouped to make harmonies of their own. Heleniums, Gaillardias, Torch Lilies and the bronzy foliage of some of the Chinese Pæonies can be most effective. To arrange interesting and beautiful groups in the borders is an art in itself. Having decided the color scheme as a whole, one may proceed to carry this out with a succession of groups each lovely in itself, and yet all subservient to, and helping towards, the general effect.

It is important to have as much green as possible for the backgrounds. In Nature one sees nearly all color as a relief against green in some or other of its many shades. The vision of a park with reds or scarlets as the predominant coloring is too hot to think about, yet it is not unusual to see something like this in small gardens, where bricks of buildings supply the red background with other colors piled on thickly.

In herbaceous borders it is better to err on the side of having the groups of one sort of plant too big rather than too small. Delphiniums, Asters, Lupins, Hollyhocks, Anchusa italica to be most effective, should be in groups as large as the size of the borders will allow. It goes without saying that most of these tall-growing plants will be at the back of the borders. Some of the larger plants should, however, be brought well to the front or the border will be too regular in outline. Also it must be remembered that form is even more important than color or, at all events, that form comes first and color should be built on to it. It is the use in the best possible way of the wealth of materials, the interweaving of the threads of form and color, that, to the artist, makes the construction of gardens so interesting an occupation.

Nearly everyone has his or her favorite colors and flowers, but some colors can be more generally used than others. Blues can be used almost anywhere, and in a blue border or garden, if one's space allows room for it, can be included as many as possible of its shades. If one does have a blue garden, one should see that it is set in green

Electric Light Speeds Up Plant Growth

E. S. MACKAY

Plants Grown at Twice Their Normal Rate with the Aid of Six 500-Watt Electric Lamps Turned on From 8 P. M. to 1 A. M. During Six Weeks' Test.

IN a six-weeks test just completed by the Westinghouse Lamp Company, in co-operation with Peter Henderson & Company, at the Henderson proving grounds at Baldwin, L. I., the value of electric light for accelerating the growth of a variety of plants was conclusively proven. Many of the specimens subjected to electric light grew during the test upwards of twice the size of similar plants receiving daylight only, and were considered by experts to be from fourteen to twenty-seven days in advance of normal growth. Of the plants selected for testing, flowers and vegetables having large leaf surfaces such as lettuce and endive, responded most readily to the stimulating effect of the light. The tests indicate

that electric light will be useful to florists and gardeners in forcing flowers for definite dates such as Christmas and Easter, and in reducing the time required for seedlings to grow large enough to permit transplanting.

"No use of artificial light, in addition to that which involves the eye, can be of greater benefit to humanity than this recently developed application to stimulating the growth and development of plants and vegetables," says Samuel G. Hibben, National Secretary of the Illuminating Engineering Society and Manager of the Illumination Bureau of the Westinghouse Company, under whose direction these recent investigations have been conducted.

"In a general way we have known that artificial light influences the growth and flowering of certain plants, but no well organized research work has been done until recently to prove whether the application of electric light was commercially feasible as a means of supplementing daylight. We now know that this stimulation of growth does not necessarily require the same intensity of light as daylight, nor does it seem necessary to reproduce exactly the color qualities of daylight. We know furthermore that plants must rest, and that the application of artificial light is advisable over only carefully chosen hours when daylight is inadequate.

*4 X Gypsophila Elegans. Sunlight and Artificial Light.
4 Y Gypsophila Elegans. Sunlight Only.*

"What this development means to the agriculturist is hard to predict. It seems, however, to promise a means of doubling the speed of development of many species, and bids fair to enable the horticulturist to bring his flowers into bloom at the time when their market is at its best. This has all been made possible by the perfection of flexible and cheap sources of light, and in it are contained advantages that seem as tremendous in their benefits to humanity and as far reaching in their scope as anything which has happened since Luther Burbank developed the Shasta daisy or spineless cactus."

On the first of September twelve varieties of vegetables and twelve of flowers were sown in shallow (3 inch) boxes, or flats, as gardeners term them. The soil used was an ordinary light sandy soil such as is generally used for starting seedlings. Two sets of flats were sown, one set for growing under the electric light and one for growing without artificial light.

The following varieties of seeds were selected for the experiment:

Snowball Cauliflower
Pasty Blanching Celery
Tender Green Bean

Transvaal Daisy
Orange Calendula
Blue Lace Flower

*A-X Cyclamen. Sunlight and Artificial Light.
A-Y Cyclamen. Sunlight Only.*

- | | |
|-------------------------|------------------------|
| Bush Lima Bean | Baby's Breath |
| French Forcing Carrot | Snapdragon |
| Davies Perfect Cucumber | Lavender African Daisy |
| Butternut Lettuce | Impatiens |
| Scarlet Giant Radish | Mignonette |
| Egyptian Beet | Wallflower |
| Rocky Ford Muskmelon | Cineraria |
| Bonny Best Tomato | Begonia |
| Golden Heart Endive | Aster |

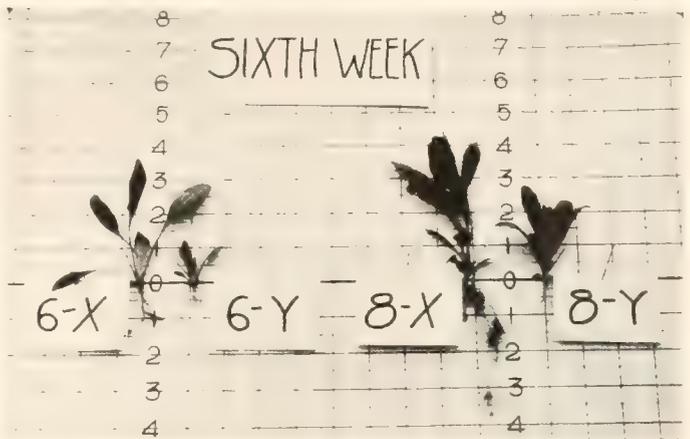

Both tests were grown under identical conditions of heat and moisture on opposite benches, with the exception that one group received the additional benefit of the electric light while the other received no additional light other than that provided by Nature. When the electric light was turned on, an oil cloth curtain divided the one group from the other. The light was switched on every night at 8 P. M., and automatically shut off at 1 A. M.

Almost from the outset, according to J. A. Fiesler, of Peter Henderson & Company, there was a marked difference noted in the germination of the seedlings under the electric light. Germination was hastened in some cases as in the beans, celery, lettuce, and endive among the vegetables and calendula, gypsophila, antirrhinum, mignonette and wallflower among the flowers, to the extent of four to twelve days, depending on the variety.

The advantage gained with the advanced germination was maintained in every case through to the end of the experiment which terminated at the end of six weeks. In some cases there was no perceptible gain in growth, par-

demand by florists, were extremely favorable. In almost every case the plants grew taller, continued in bloom longer and were sturdier than those that did not receive the benefit of the artificial light.

GARDEN DESIGN

(Continued from page 275)

surroundings and, with the exception of, it may be, a little white, it should be kept to blues. Blue flowers with green turf and gray stone-walling are always beautiful together.

As in Eastern embroidery, one may, in parts of the principal borders, work up to a riot of the richest colors. Deep blue and purple Delphiniums, orange Lilies, crimson Pentstemons and Hollyhocks (crimsons are generally safe, but beware of scarlet!), apricot and yellow Day Lilies, with always plenty of green foliage, and the bronzy leafage of purple-leaved Plums and Pæonies will make a brave show. One must not forget that color is to be obtained not only from flowers, but that numbers of trees, shrubs and plants are invaluable for the coloring of their foliage.

4-X *Gypsophila Elegans*. Sunlight and Artificial Light.

ticularly in the root crops including beet, carrot and radish.

That there is certain analogy between the radiant energy of sunlight and that of an incandescent electric light was definitely established by the fact that the chlorophyll in those plants which received the additional electric light was more active. The foliage presented a richer, greener, more turgid, and vigorous appearance than those that were denied the advantage of the additional light. Also in the case of the vine crops, cucumbers and muskmelon, the stems of the plants were heavier and stockier than the plants grown without the electric light. In this experiment, the fact was established that all plants presenting a large leaf surface are greatly stimulated by the additional electric light, as in the case of the leaf crops, viz., lettuce and endive.

Preliminary tests on the forcing plants by the use of artificial light were conducted by the Westinghouse Company at Columbia University, under the auspices of Prof. Hugh Findlay of the Department of Agriculture of the University. The results on such plants as Boston fern, Calla lilies, rose geraniums and others which are much in

Collecting Orchids in Central and South America

THE orchid collection of the Missouri Botanical Garden has always been a notable one, and after the acquisition of the Brownhurst collection, through the generosity of the late D. S. Brown, it took first rank in this country for the number of varieties as well as quantity of plants.

The general public is apt to judge such an exhibition from the standpoint of color and quantity of bloom rather than the rarity of the plants, and for this reason it seemed desirable if possible to augment considerably the number

houses and in forests close at hand. In Yacopi, in the Departamento Cundinamarca, the villagers even presented a collector with forty cases of plants. A present-day collector, however, must rely upon the natives exclusively, making his headquarters at the nearest village and waiting with all the patience at his command for the return of the natives with the coveted orchids.

The best time for collecting *Cattleya Trianae*, according to Cyril Allen of Bogota, is during the dry season (November to March). The flowering season, "Varanillo" ("little dry season"), which is from the end of July to September, is then over, and if collecting is done during this period it is possible to select the best types.

Cattleyas do not grow in the hot country, but in the foothills of the Cordilleras, from 2,000 to 6,000 feet altitude, where the mean temperature is 65-67° F. Most *cattleyas* are entirely local in their distribution, certain species being confined to a small given region and disappearing completely when this area is passed. They inhabit the topmost branches of the *Aquapa* (*Bombax*), 150-200 feet in height, where there is plenty of sunlight. Even in the dry season they are subjected to heavy dews at night which more or less prevent shrivelling. *Cattleya Mendelii* has been found growing upon rocks too hot for the naked hand, suggesting that most *cattleyas* need abundant sunshine.

Cattleya Percivaliana grows much better upon rocks and cliffs overhanging streams than upon trees. Other *cattleyas*, such as *C. Trianae*, prefer the topmost branches of trees. They may be found in either the crotches or branches, upon the sides of the main trunk, or in many cases surrounding the limbs of the smaller branches where their roots tenaciously hold them fast against the strongest wind, often making it necessary

Cyril Allen and G. H. Pring, Collecting *Odontoglossum Flavescens* in the Andes of Bogota

of more showy orchids, especially *cattleyas*. During the war, however, practically all the collectors of orchids, particularly in South America, went out of business, and it is no longer possible to buy these native plants through local agents. Consequently, the only way in which they can be obtained is to send a representative direct to the country where these particular orchids are grown, in the hope that by a fortunate combination of circumstances, he may secure enough of these plants to make the trip worth while.

Another factor which has greatly restricted the importation of native orchids into the country has been the restrictions imposed by the Plant Quarantine Act, and indeed it was not possible to consider securing *cattleyas* from South America until this difficulty was overcome. However, because of the standing of the Missouri Botanical Garden, the Federal Horticultural Board granted a special permit, allowing orchids collected in South America and Panama to enter at New Orleans and come direct to St. Louis, where they could be inspected, instead of following the usual regulations. With the way clear for the delivery of the plants to the Garden, George H. Pring, Horticulturist to the Garden, began at once to make preparations for the trip.

Early collectors of orchids in Colombia, such as Schlim, Blunt, Linden, the Klablock Brothers, Chesterton, Lehmann, and Kalbrayer, had no difficulty because of the abundance of accessible plants. During these easy-collecting days the commercial *cattleya* was found growing upon

Orchids En Route on Pack Mule from Natasima to Upper Magdalena River

for the natives to pry the plants loose, with attached bark, by means of their machetes. If there are many plants upon a tree, there is no hesitation about cutting the tree down. Plants are not so plentiful at the present time, however, and it is truly an orchid hunt. Nothing but the trained eye of the native Indian can find the *cattleyas* in

their concealed locations. According to authorities, there are now more commercial cattleyas in the United States and Europe than growing in their native environment in Colombia.

The appearance of the orchids as collected is rather disappointing to the orchid enthusiast who has been used to orchids in the greenhouse. Masses of dried-up black pseudo-bulbs, old flowering spikes, and dead leaves present anything but a pleasing appearance. The dark green color to which we have become accustomed in orchid houses is replaced by a foliage of yellowish green.

The following extracts from Mr. Pring's diary give a graphic picture of what it means to obtain orchids under present-day conditions:

"I left St. Louis, April 1, bearing letters of introduc-

Cattleya Trichomanes Growing Upon Trees in the Central Andes.

tion from the Colombian ambassador at Washington to Government officials in Colombia and from Secretary Wallace to the Minister of Agriculture; also a letter from the Colombian Consul at St. Louis. Sailing from New Orleans on the Steamship 'Heredia,' I arrived in Cristobal, C. Z., April 11. I sailed from Cristobal aboard the Steamship 'Sixaola.' Aboard ship I was particularly fortunate in meeting Norman Black, who was making his way back from the States to Bogota. During the conversation I informed him of my mission and likewise mentioned my letter of introduction to Cyril Allen, who proved to be a personal friend of Mr. Black. The entire trip from then on was under the guidance of Mr. Black. We arrived at Cartagena, the first Colombian port, the following day. Leaving Cartagena we arrived at the port of debarkation the following day, Puerto Colombia. We left here at 5:30 and reached Magdalen town, Barranquilla, at 11:30 P. M. At the river steamer office we were informed that all river rates had been raised. However, we booked on the 'Ayacucho' to sail that evening. On leaving the hotel Black said: 'Pring, I forgot my bed equipment.' On asking for an explanation I found that bed equipment for the trip had to be purchased, consisting of a pair of sheets, mosquito bar, pillow and pillow case,

and native straw mat, or 'petate,' supposed to take the place of the comfortable mattresses of home.

"The Magdalena river boat was rather interesting to a St. Louisian in that it was an exact replica of those used on the Mississippi River. In fact we later found that these boats are built in towns along the Mississippi and shipped to Colombia to be assembled. We were shown to our cabin de luxe which was on the uppermost deck. The stateroom equipment consisted of an American iron cot, guiltless of mattress and covers, upon which we placed the recently acquired bedding; a wash stand, electric lights, and fan. The two doors were screened but the windows were bare. We left at nine o'clock. We found it impossible to walk upon the upper deck inasmuch as the air was filled with thousands of sparks. I was informed that the boat was of the wood-burning type and in passing backwards and forwards to our cabin we took the chance of our clothes being set afire by falling sparks.

"I had been advised by Americans to buy American canned food and an American ham before leaving Barranquilla, but on suggesting this to Black he told me that I might as well get used to native food, as I would have to eat it for several months; that I would soon become accustomed to, and learn to like, many of the native dishes. When once accustomed to meals as served on the boat I concluded that he was right, as I very soon began to like the various ways in which the banana was served, either

Terrestrial Orchids Growing in Andes of Bogota.

as fritters, pies, or as a dessert cooked with sweet juices. Among the vegetables the most common was the yucca (Manihot). This is cultivated as a companion crop with corn. Roots from the fully developed plant are eaten, in shape resembling the turnip and much more farinaceous than the ordinary potato. The meat served would not suit the American palate, inasmuch as the cattle are killed at five o'clock in the morning and served the same day. It is very dark in color and always hard and stringy. Eggs are served three times a day and the first question asked by the waiter is 'Como se huevos, señor?' Coffee is served in the form of 'Cafe con leche,' about a table-

spoonful of concentrated coffee being poured in the cup, after which boiling milk is added. For dessert various tropical fruits are always offered, such as mangoes, avocado, pineapples, and papaya. During the forenoon and afternoon various refreshing drinks are served, prepared from the native brown sugar; others are also made from oats.

"Our first port the following morning was Calamar, which is the river port for Cartagena. The next port was La Florida where we stopped to take on wood for fuel. This performance took place about every five or six hours, day and night, on the trip.

"The vegetation on each side of the river for the first two or three days was very disappointing and uninteresting, because of the lack of rain in this part of the country. What vegetation was present presented a yellow appearance.

"The next port of interest was La Gloria. Here one was gratified in having sufficient time to view the native houses. These resemble stucco but Black informed me that the skeleton is made of bamboo and the stucco made from river sand mixed with cow manure. From here on the vegetation began to be of interest, the mahogany delta appearing. After leaving the town of Gamarra we began to view some very picturesque scenery, with the western Cordilleras appearing. The next important town was Bodega Central, the river port for exporting cargo from the prosperous town of Bucaramanga, the latter shipping 250,000 bags of coffee to the United States annually. From Bucaramanga to the river port is a four-day mule-back trip.

"The next town was Puerto Wilches, a river port for the exporting and importing of both cargo and passengers to and from Bucaramanga. It possesses a railroad of seventeen miles which was intended when begun to connect with Bucaramanga, but the remaining 120 miles is by mule-back. During the rainy season the Bodega Central route is used, combined with freighting over the river Lebrija.

"The vegetation here becomes very interesting, presenting a darker green appearance than lower down the river. Lots of trees, including the native cedar, bombax, lignumvitæ, and closer to the river, the giant bamboo. Here we passed the river Lebrija where we unloaded some American machinery. I was particularly interested in some large heaps of the palm seed which I readily identified as the ivory nut palm. It is from this region that the ivory palm is exported to the states for the purpose of making buttons.

"After leaving this river port I had my first experience of seeing orchids upon trees, together with various other epiphytes, including bromeliads, *Nephrolepis*, *Polypodiums*, mosses, etc., the young growth being impenetrable. Particularly noticeable was the rattlesnake plant, leaves of which are used for wrapping the native brown sugar in cake form. Various species of *Heliconia*, presenting their bright orange colored bracts, were very picturesque. The scenery, with the mountains in the background, was almost beyond description.

"We finally reached the uppermost port of the Lower Magdalena River, La Dorada. From here we caught a wood-burning train to Beltran, a distance of sixty-five miles. The object of this railroad is to avoid the rapids at Honda which cause the river to be unnavigable at that point. Honda is likewise in a big coffee-shipping district. Arriving at Beltran at twelve o'clock we again went through the unpleasant pandemonium of transferring baggage to the boat on the Upper Magdalena River. We arrived here after a very picturesque trip. One of the

interesting towns is Ambalema, situated in a big tobacco-growing district noted for its native-made cigars; also for its pottery. We arrived at Girardot the following morning. The distance traveled from Barranquilla to Girardot was 700 miles. After going through the customs, we enjoyed a very pleasant rest at the Pension Inglesa. The next step of our journey was started the following morning, to Bogota. Leaving at 7 A. M. by train, we started our upward climb from the tropics, 600 feet above sea level, to the temperate climate of Bogota, 8,500 feet. We got as far as Facatativa, where we were obliged to change to another train because of a difference in rail gage. We finally arrived at Bogota at five o'clock, on May 1, exactly one month from the time we left St. Louis. After traveling in the tropics, at Bogota one feels the effect of the altitude in the form of headaches and increased heart action. The 'Sabana' of Bogota is extremely picturesque, surrounded by the eastern Andes. The population is approximately 140,000. During my first week in Bogota I suffered from a slight attack of ptomaine poisoning, after which I had many consultations with Norman Black, who kindly consented to act as my agent, and with Mr. Cyril Allen, who very kindly put me in touch with his native collectors who could obtain the varieties of orchids wanted in quantity for the Garden. I was advised by both Black and Allen not to go with the native collectors to gather orchids, inasmuch as I would be exposed to malaria, typhoid, etc., combined with the danger of being absolutely at the mercy of the natives of that region, especially as my knowledge of Spanish was extremely limited. Again, the word would undoubtedly be passed in advance that an 'Americano' was coming and prices would be raised in proportion.

"In view of the fact that Cyril Allen had collected and exported orchids for the past fourteen years, and that Norman Black, through his experience with the natives in dealing in coffee, knew of their financial trustworthiness, I decided that their advice was final. As Mr. Allen was leaving shortly for Europe, quick action was necessary. Within two weeks I was in touch with a native collector of *Cattleya Trianae* and another to collect *Cattleya Schroederae*, in two widely separated regions. To collect these two varieties in the quantity desired Mr. Allen stated that he would have demanded six months' time. On the other hand, I was contemplating a six weeks' stay in Bogota. The transactions with the natives were accomplished by Allen and Black, it all being carried on in the native tongue. I was present at the conference, but only as a guest of Black, and not supposed to be interested in the orchid transaction. In other words, Black was the agent who wanted the shipment for export. This meant that the Garden got the benefit of strictly native prices, which it would have been impossible for me to obtain.

"The next difficulty for me to settle was the question of financing the natives, who had to take sufficient money to buy the plants from the collectors in the fields. Norman Black strongly advised me not to advance any money. Allen on the other hand, stated: 'If you don't advance the money to buy the orchids, it is impossible to expect the natives to bring them to your base of operations.' So I finally decided to advance sufficient money to purchase the plants in their native habitat. After arrangements were made by telegram and later with the native agent at the small village of Natagaima, he presented himself at Girardot to receive the first payment. On seeing him Black recognized him as one of his best coffee shippers, which was much of a relief to me as he had always found him absolutely reliable."

(To be continued)

Wildwood Beauties for Our Lawns

CHARLES H. CHESLEY

MANY of the plants found in our northern woods make very pretty and profitable perennials for shady places about the lawns and grounds. They are easy to grow, in most cases, and once established will increase with the years. If there is an out-of-the-way corner, with considerable shade, no better place can be found for native plants. I am speaking particularly of the woodland plants. There are, as well, open-country and prairies plants which may be planted in the open spaces of the lawn and they will require very little attention.

Nearly all of our natives, when removed to a different environment, improve with the change. This does not mean, of course, that a species found in sandy soil should be removed to a heavy clay location. Prepare the soil with plenty of fertility but have it conform in texture with the native habitat of the plant, then success is assured.

In this corner, which we are going to plant in imagination, and which is in reality a composite of two or three wild gardens we have in mind—the soil will be prepared by hauling several loads of woodland mould and spreading it evenly beneath the stand of trees. Over this leaf-mould, we shall spread well-rotted manure from the cow stable. Almost all plants take kindly to rotted manure and the extra size of plants and flowers well repay the cost. So, we have the place prepared with the soil mellow and easy to work. This is accomplished by using nothing but fine soil from the woods, no large flakes, and then working with a hand cultivator. Of course, a horse cultivator cannot be used between the trees. Having the soil mellow to a depth of six inches, we proceed to get the plants, which may be either in Spring or Fall. If in the Spring, it should be very early, while any time during the Fall will usually prove satisfactory. We shall assume that the shade is dense, but preferably it should not be that cast by evergreens. Certain plants grow beneath evergreens but a larger variety will thrive beneath shade which is partly, at least, cast by deciduous varieties. I should not set plants in masses but should try to have many different kinds in a hit-or-miss pattern, the Summer and Fall bloomers mixed with those that open in Spring. It often seems that Nature grows two plants in the same place, for certain it is that Fall-blooming plants seem to grow in the same place that was occupied by some delicate Spring beauty.

First we shall set the plants which bloom early in Spring. The trilliums, known as Wake-Robin and Birth-root, should certainly have a place. These grow from a tuber-like rootstalk and may readily be transplanted. Of these perhaps the handsomest is *Trillium erectum*, with showy purple blooms. The one thing against it is its rather disagreeable odor. *T. undulatum* is another handsome species, having red and white flowers, hence the name Painted Trillium. The Snow Trillium, *T. nivale*, has handsome white flowers. Several other species of Trillium are also found throughout our northern and eastern states, all of which take kindly to cultivation. Found in the same woodlands are Solomon's Seal, *Polygonatum biflorum* and *P. commutatum*, and the similar *Streptopus roseus*. *Maianthemum canadense* grows in similar localities and should find a place in our corner. All of these are plants of the Lily family, to which perhaps we should add *Clintonia borealis*, that has rich yellow blooms. The above are Spring flowers.

Along with the plants named will be found several members of the Orchis family. Those which are found in woodlands, and therefore thrive in the shade, are *Orchis rotundifolia* and *O. spectabilis*. The latter is one of our most beautiful native plants. Several species of Fringed Orchis, particularly *Habenaria blephariglottis*, with white flowers; *H. ciliaris*, with yellow blooms, and the handsome pink-flowered *H. fimbriata*, should also be planted. I shall not enumerate any more of this family, though there are many others which are worth transplanting to the private grounds.

During the early Summer the flower procession of the woods seems to pass to the shrubs, although there are several species of woodland violets, which could be naturalized and used to blossom with the liliaceous plants mentioned. Later, still, the shade-loving species of Golden Rod and Aster take up the procession and continue it until the frost comes. One can scarcely name all the desirable plants of the woodland but many beauties are found in every locality.

The thing to do then, is to prepare the place for the plants, then go out in the woods and take up whatever is desired. Some of the species, which are most beautiful, are, of course, only local in the native state. Many of these may now be procured from nurserymen, who are beginning to appreciate the beauty of our native plants, as the European florists have for many years. It really matters little what is transplanted, the plants are sure to prove a joy all Summer and will improve with the years.

As to the care of such a garden of wildings, once it makes a start there will be little required. The first Winter a mulch of leaves and straw should be used; in fact, it is a good plan to provide some sort of covering every Fall, for in the woods the leaves provide a natural covering. Perhaps the leaves from the shrubbery will be sufficient but one should be sure there is a good covering and that it will stay in place. In the Spring this covering can be raked off, and, if a little work is done about the plants after they come up, they will well repay for the labor. Once in three or four years a Fall coat or rotted manure can be added.

NOTES FROM AN OLD COUNTRY GARDEN

(Continued from page 274)

of the highest esteem for its autumnal tints is *Parrotia persica*. This belongs to the same natural order (*Hamamelidaceæ*) as the Sweet Gum; it seems perfectly hardy and the large leaves assume glowing shades of orange and crimson before they fall.

Also most attractive at this time is the deciduous Cypress (*Taxodium distichum*) which, though a native of the southern parts of North America, is quite hardy with us. This is, moreover, a tree that has grown and prospered for many years in our London parks under conditions which few of the *Coniferæ* can endure. There and elsewhere are some noble specimens, some 100 feet in height, and when the pale-green, yew-like foliage turns color prior to their fall, the whole tree becoming a towering spire of a glowing foxy red, it is a most arresting sight.

Unlike most *Conifers*, *T. distichum* enjoys a swampy soil and will even thrive in shallow water.

Foreign Exchange Department

CORNUS KOUSA.—There is a remarkable, if not very large, group of Cornels represented in gardens by this species, the beauty of the inflorescence of which is imparted by four or more large bracts, not by the flowers themselves. Of these Cornels, the one most amenable to cultivation is the Japanese species *Cornus Kousa*. The real flowers are very tiny and crowded into small dark cones, each of which is surrounded by four beautiful spreading bracts. Each bract is 1 inch to 1½ inches long, and creamy white. This deciduous small tree or shrub is at its best in June, when the inflorescences ("flowers" one usually terms them) are fully expanded and stand erect in rows along the branches. It then presents an aspect of striking beauty. The fruit is a fleshy strawberry-like mass in which the seeds are embedded, and is really a development of the little cone on which the flowers are set. The leaves are about 3 inches long, with undulated margins and conspicuous parallel veins. The real drawback to the success of this Cornel in gardens is the mild, soft weather, of which our normal Winters contain so much. The tree is thereby often excited into prematurely active growth, only to be injured by later frost. Otherwise it is very hardy. It thrives best in rather elevated districts. Young plants are usually imported from Japan.—*The Garden*.

THE VIOLET CRESS (IONOPSISIDUM ACAULE).—The value of this dainty free-flowering annual as a carpet plant is too often overlooked. When scarcely 3 inches high and about eight weeks after the seeds are sown, the plants throw up abundant masses of pretty violet-colored blossoms. As an edging plant to borders, this little annual is invaluable, while it is an excellent subject for carpeting between Roses and Gladioli. The ground round about Gladioli is generally uninteresting until the flower-spikes expand, and here the Violet Cress, as this plant is popularly called, does great service. Where the seeds have been sown early in the Spring it is often possible to get a second display of blooms towards the end of the Summer. All that is necessary is to pull out the plants as soon as they have seeded and rake over the ground. The self-sown seedlings will very quickly appear if there is sufficient moisture to start them into growth. If the weather is hot at the time it is a good plan to erect a temporary shade over the bed and remove it as soon as the seedlings appear. The Violet Cress may also be employed for growing between the flags of a stone path, while it is essentially a good annual for the rock garden. It is a favorite plant, too, for growing in deep pans in the unheated greenhouse or in the frame, and the specimens grown in this manner come in very handy for household use. A suitable compost may be made up of equal parts loam and leaf-mould, with a heavy sprinkling of sand.—*Gardening Illustrated*.

SIEBOLD'S PRIMULA.—The plant usually grown in gardens as *P. cortusoides* is almost always *P. Sieboldii*, a handsome but not over-hardy Japanese species, of which there are quite a number of excellent forms in commerce, with flowers varying in color from pure white to deep purplish rose; some of the sorts, and those not the least handsome, have fringed petals. It is rhizomatous, and these rootstocks are very easily damaged by frost, especially in wet soils. For colonizing in fairly open woodland, however, or for a sheltered corner in the rock garden this Spring-flowering species is first-rate.—*The Garden*.

PENTSTEMON HETEROPHYLLUS.—Beds filled with this Californian sub-shrub are very pretty, owing to the profusion of flowers borne and their distinct and beautiful steely-blue color. These appear on graceful stems from 18 inches to 2 feet in height, and, whereas in many instances a plant will produce every flower of this lovely blue, others display flowers of a purple-blue shade. Although this variable coloring is much admired by many I prefer the uncommon and lovely blue flowers. Where the stock is increased by cuttings, the plants it is intended to propagate from should be marked whilst in bloom and the cuttings taken at the end of September. This plant also ripens seed freely.—*Gardening*

ROSA MOYESI AND A CHARMING SEEDLING.—Such a graceful, yet strong, hardy shrub needs no fence or support, and is certainly seen to the best effect when spreading its arching growths in the open, and where little or no pruning is required. Unique in the color of its dark-red flowers and beautiful leaves, this Chinese Rose is perhaps the most striking and handsome of the wild species. Early Autumn again sees this Rose laden with attractive, large, orange and red, bottle-shaped fruits, each from 1 inch to 2 inches in length. A few seedling plants given to me by a friend two years ago are also blooming for the first time, but whereas the beautiful form of leaf and stem is the same as in the mother plant, the flowers are of a fascinating cerise when fully open,

and reddish-pink in the bud. These seedlings are really handsome and of great value for our gardens, but the true species is so striking in itself that we do not anticipate its being surpassed by any of its progeny. Where space is available it is both pleasing and instructive if the various wild species are grouped in close proximity.—*Gardening Illustrated*.

THE LEAD PLANT (AMORPHA CANESCENS).—I like this graceful Missouri plant, which I saw growing in a rock garden recently. It grows about 18 inches to 2 feet in height, has spikes of blue-purple flowers, with protruding orange stamens and pretty hoary leaves and flower-stalks. It is a plant one only sees on rare occasions, yet one entitled to a place in the front of the hardy-flower border.—*Gardening Illustrated*.

INCARVILLEA DELAVAYI.—In well-drained soils this hardy plant is very satisfactory, and is so distinct that it should find a place in villa gardens, where there is often not too much variety. It does not require an abundance of food. I have had it doing well close to an evergreen hedge where the ground was extremely dry during a great portion of the Summer. The fleshy roots cannot endure much stagnant moisture during the resting period, therefore unless lifted at the beginning of the Winter and stored in a frame it is liable to perish. It will, however, be quite satisfactory if grown in this way, planting out in March or early in April. Fortunately, it is easily raised from seeds, which should be sown early in Spring and will bloom the following year. An ideal place for this *Incarvillea* is in front of an evergreen shrub or tree, where the fine color and distinct beauty of the flowers are fully displayed. Many more would grow this beautiful plant if they were acquainted with its merits. At the present time it is neglected by the owners of small gardens.—*Gardening Illustrated*.

THE PLUME POPPY (BOCCONIA CORDATA).—Very handsome are the Plume Poppies with their large, deeply-lobed leaves, of a gray-blue tint on the under-side, and about the size of a Vine leaf. They are also graceful, tall-growing plants, reaching from 8 feet to 10 feet in height, in good soil, each growth terminated by a 4-foot inflorescence of orange and cream.

Good effects may be obtained by growing it in hardy-flower borders, where the latter are large and possess a good depth of soil. The border is, however, not the only place where these subjects are seen to advantage, for they look remarkably well as large, isolated groups in the foreground of trees or evergreen shrubs, and even planted among dwarf shrubs. The Plume Poppy is a deep-rooter, and therefore is not greatly affected during periods of drought; nevertheless, good ground it does enjoy at all times; also a sunny position.—*Gardening Illustrated*.

GAULTHERIA PROCUMBENS.—This is a pretty little peat-loving shrub of the Ericaceous order, a native of the Eastern States of America, and introduced 150 years ago. It is popularly known as the Creeping Wintergreen, or Partridge Berry, and it has long been valued for the "oil of winter-green" extracted from its fruits and used by chemists for the flavoring of drugs and other purposes. A leaf crushed between the fingers at once reveals the familiar odor of that extract. *G. procumbens* is a charming subject for cool, shady places where it may be used for associating with other lowly plants of a like nature, or for carpeting the ground about dwarf Azaleas. It does not often exceed 6 inches in stature, and is usually not much more than half that height, the little tufts of leathery, dark green leaves being borne on erect stems, which rise from the creeping roots. The almost cylindrical flowers, which appear in clusters at the leaf-axils in late Summer and Autumn, are large enough to be conspicuous and of a fresh pinky-white. These are followed by berries as large as those of the Holly and of much the same color. This is, perhaps, the easiest of the smaller *Gaultherias* to satisfy. It does well in lime-free loam and leaf-mould.—*Gardeners' Chronicle (British)*.

PRUNUS TRILOBA.—This species is one of the best members of the *Prunus* family for forcing, and lends itself to many uses, not the least among them being its value as a cut flower or vase decoration.

Young plants should be procured as soon as possible, potted in a suitable mixture when received and stood in a sheltered spot out-of-doors.

Any time after the New Year is early enough to commence forcing them, and, as in the case of all shrubs that are forced, they should be taken into an intermediate house for a week or so before being introduced to the forcing house. A temperature of 65° is suitable—in a higher temperature the plant will not give its best, and constant syringing is necessary until the flower buds begin to open. It is well then to cool the plants down at this stage, and if this is done carefully the flowers will remain for three weeks or a month in perfection.

After flowering it is well to encourage the development of growth by placing the plants in a warm Peach house, when, after the severest frosts are over, they may be placed out-of-doors in a

sheltered situation. If they are to be retained for forcing the following year they should be trained carefully, removing all unnecessary old wood immediately after flowering; giving the roots some slight stimulant during the Summer. Planted outside in a shrubbery this *Prunus* is of great value—both for its hardiness and its wealth of double pink flowers in April.—*Gardeners' Chronicle (British)*.

SPIRÆA JAPONICA.—The type species of the group of shrubby *Spiræas* included under the above term is not so well known, nor is it so attractive as some of its varieties. The most popular of the latter is Anthony Waterer, a sub-variety of *S. j.* var. *Bumalda*, one of the handsomest of its race, and especially valuable on account of its late flowering. The broad, crimson-carmine corymbs of this shrub, much more brilliant than those of the dwarfed *Bumalda*, are well known, and this season they happen to be especially good. This is due not only to the abundant rains of the later Summer, but also to the fact that there has not been sufficient sun to bleach the rich color of the flowers.

One of the most charming varieties of *S. japonica* is *S. j. alba*, or, as it is sometimes called, *S. callosa alba*. This is a very distinct little shrub—so distinct, indeed, that some class it as a separate species. It does not exceed about a foot in height, and the many slender, upright branches, with their pale, almost emerald, green leaves, bear a profusion of white flowers in terminal corymbs. *S. callosa alba* blooms freely and late, it is perfectly hardy, and easily satisfied as to soil and situation.—*Gardeners' Chronicle (British)*.

VIBURNUM TOMENTOSUM.—It is not always the most strikingly brilliant colored foliage that proves the most effective, and this idea was impressed firmly on my mind when looking at a large bush of *Viburnum tomentosum* a few days ago. The wonderfully artistic coloring is superb. Usually one regards this plant as a flowering shrub only, and certainly as such it is of the very highest merit, but one must also admit it holds a high position for the coloring of its foliage, which ranges from the deepest coppery red on the older leaf surfaces through lighter shades of red and deep pink to the younger leaves that are of pretty light, bronzy green flushed with deep pink markings according to age. The stem and growths are bronzy brown, whilst the leaf-stalks are very deep red, and then, to finish off, there is the paler under surface suffused with pink. The whole is marvellously toned down by the leaf tomentum. The variety *V. tomentosum plicatum* is almost as beautiful, but the leaves are of somewhat smaller size.—*Gardeners' Chronicle (British)*.

COREOPSIS GRANDIFLORA.—Sow a few seeds of this annual now in a cool house. When they are large enough, prick off the seedlings into small pots of loamy soil, and grow the plants on a shelf in any airy house until they are well rooted. They may then be transferred to 48-sized pots, and, if grown hard in a cold house, will give a welcome bunch of cut flowers in the Spring, or, if carefully staked, will make quite goodly shaped pot plants.—*Gardeners' Chronicle (British)*.

THE PERIWINKLES.—Plants of the small-leaved species, *Vinca minor*, are very widely grown in gardens. The *Vincas* are very accommodating plants and among the most useful, as in most gardens and pleasure grounds there are positions where neat-looking plants will not thrive, and in such places weeds soon take the lead and become a nuisance. Under such trees as Cedars, especially under the Cedar of Lebanon, it is a difficult task to induce a nice green undergrowth, but I have found no difficulty when employing *Vinca major*. The plants soon formed a dense green carpet which, speckled with the lovely blue flowers, during a part of April and throughout May and June made a charming picture. I once had occasion to carpet a quite open border—the front portion—with this variety, and the plants grew so rapidly in the mixture of soil, old lime rubble and leaf-mould that at one end, adjoining a wall, the shoots grew up the latter several feet and were then assisted by neat supports, the effect being very pleasing, as the position was one near to a door leading through the wall from a shrubbery to a walled-in garden. Propagation is quite easy.—*The Garden*.

THE CORSICAN HEATH.—The *Ericas* come to the garden lover with so many and varied charms that selection becomes a matter of real difficulty. Perhaps one's peat patch is rather confined, and therefore one has to be specially critical before admitting a new-comer. One will not be wrong in planting *Erica stricta*, the Corsican Heather, for there is no season in the year when it does not look attractive, though most of all when the ends of the shoots are decked with their pale red flowers in Autumn. It is notable among Heaths as a very erect grower and, though of compact habit, capable in course of time of attaining a stature of 3 feet, or even considerably more. In addition to the flowering season, the plants are extremely decorative during Summer when covered by the young foliage.—*The Garden*.

NERIUM OLEANDER.—This handsome flowering shrub, with its glossy, evergreen leaves, is frequently grown in a warm greenhouse, where it becomes a prey to mealy-bug, scale, thrips, etc. Grown outside during the Summer and Autumn, with the protection of a light, airy house in the Winter only, it is much less liable to become infested with these pests, and is a most useful plant for late Summer decoration in the formal or terrace garden. Well-grown plants in tubs make beautiful subjects for this purpose when in flower, and are not unattractive even when not in bloom.

To produce good specimens, copious watering and liberal feeding are necessary during the period of active growth, the plants being kept slightly dried after flowering, so that the new growths are not incited to flower.

The flowers are produced in terminal, racemose cymes from well-ripened wood, and the new growths develop at the base of the spray of blossom at the same time—hence the only pruning that is needed is the removal entirely of any worn-out branches to allow their places to be taken by occasional new growths that develop at the base.

When the plant finally becomes too leggy, it can be cut hard back in early Spring, but it will not then flower during that season. Cuttings of matured shoots root freely if inserted in small pots and placed in a close frame, and a few cuttings should be struck yearly and the plants grown on so that old and worn-out specimens may be discarded.—*Gardeners' Chronicle (British)*.

Brief Horticultural Jottings

A writer in the *Gartenwelt* (Berlin) draws attention to the fact that, although in ancient times collections of plants existed which could be considered to be the equivalent of the modern botanic gardens, the range of the plants must have been very limited before the discovery of America or the opening up of the continent of Africa. In the sixteenth and seventeenth centuries, however, the movement towards botanic gardens was rapid, and in 1560 there were already fifty of such gardens in Italy, the first, at Pisa, having been founded in 1543. The one at Padua was founded in 1546, and is the oldest still existing in the world; it contains a "Chaste tree" (*Vitex Agnuscastus*) said to be 370 years old. The garden at Bologna was founded in 1568, and those at Rome and Florence were commenced about the same time, while the one at Leiden, the famous Dutch University town, dates from 1575.—*Gardeners' Chronicle (British)*.

One pretty good test of the hold that plant growing has on human nature is the extent to which it is practiced by children. For while they may represent a negligible factor in the commercial field today, those same children are the potential growers and buyers of the future. It is therefore interesting to find that in the Junior Project work carried on by Cornell University among 14,189 boys and girls in New York State last year, more than 2,400 projects were gardens. This brings plant growing second among the agricultural activities, poultry raising coming first with 3,056 projects. These figures are the more significant when it is noted that 40 per cent of the whole number of projects (or 5,677) are in the indoor or home making rather than the outdoor or agricultural class.—*Florist Exchange*.

The famous Washington elm, under whose branches George Washington took command of the Continental Army, toppled over a few weeks ago. Thus the famous tree passes into history. A number of months ago the tree was given up as "dead" after experts had examined it and declared it was beyond saving. Today, in a mild wind, the elm fell over under its own weight, its badly rotted trunk proving unequal to the strain upon it.—*New York Herald*.

While supervising the construction of a series of stone houses, Jocelyn Davidson, architect, noticed some peculiar cavities in certain of the stones, and on further investigation, found that these cavities contained dried blossoms. The holes are only discovered on breaking the stones, so that it seems certain that the flowers have been completely sealed in their rocky tomb. On the other hand, the stone is of the Silurian Dolomite formation, some 50 or 60 million years old, as geologists reckon time, while the flowers are of a high development and much later in origin. They appear to be akin to the common wild Rose of Canada, but different in color, the majority being of a rich dark crimson, while some few are yellow. Fossil flowers are, of course, not unknown, but these are dried as if pressed in a book, except that the petals are rolled together instead of being flat. The find appears to be entirely novel and it has been referred to the university, where it is now being considered. The stone comes from Owen Sound, where there are large quarries of this variety of limestone.—*Toronto Star*.

National Association Of Gardeners

Secretary's Office, 286 Fifth Ave., New York

The aims of the association are to elevate the profession of gardening by improving conditions within it.—To cement a closer bondship among all engaged in, and interested in, gardening—to create a greater confidence between employer and employee.

Co-operating with the Massachusetts Agricultural College, the association conducts a course in training young men for the profession, whereby they obtain theoretical knowledge as well as practical experience.

SERVICE DEPARTMENT

The National Association of Gardeners operates a Service Department to serve country estate owners in an advisory capacity in adjusting problems which occasionally arise in the maintenance of country estates.

Owners desiring the services of gardeners, thoroughly versed in all phases of the profession and qualified to assume the responsibilities the position calls for, as superintendent or gardener, should apply to this department.

OFFICERS 1923

President JOHN BARNET, <i>Sewickley, Pa.</i>	Vice-President ROBERT P. BRYDON, <i>Cleveland, O.</i>
Secretary M. C. EBEL, <i>New York, N. Y.</i>	Treasurer MONTAGUE FREE, <i>Brooklyn, N. Y.</i>

TRUSTEES (For 1923)—Thomas W. Head, D. L. Mackintosh, Arthur Smith, New Jersey; Robert Cameron, Massachusetts; Andrew L. Dorward, Rhode Island.

DIRECTORS—(To serve until 1924) William Hertrick, California; George H. Pring, Missouri; Robert Weeks, Ohio; Thomas Wilson, New York; Harold Bryant, Connecticut; Harry Cartwright, Michigan; H. Ernest Jowner, New York. (To serve until 1925) George Wilson, Illinois; James Stuart, New York; William Kleinheinz, Pennsylvania; Edwin Jenkins, Massachusetts; Carl N. Fohn, Colorado; Joseph Tansey, New York; John Tonkin, Pennsylvania. (To serve until 1926) Alexander Michie, New York; George F. Stewart, Massachusetts; Theodore Wirth, Minnesota; George W. Hess, District of Columbia; R. P. Brydon, Ohio; William C. Rust, Massachusetts; Charles Schroll, Wisconsin.

Busch, Dr. George T. Moore. *W. Virginia*—Mrs. Arthur Lee. *Georgia*—Asa G. Candler, Jr., G. Gunby Jordan. *South Carolina*—Robert S. McLean.

LOCAL BRANCHES

NEWPORT, R. I.: Andrew L. Dorward, chairman; Frederic Carter, secretary.

ST. LOUIS, MO.: George H. Pring, chairman; Hugo M. Schaff, secretary.

NASSAU COUNTY, L. I.: James Duthie, Oyster Bay, chairman; John McCulloch, Oyster Bay, secretary.

BOSTON, MASS.: Robert Cameron, Ipswich, chairman; W. N. Craig, Weymouth, secretary.

WESTERN PENNSYLVANIA: James Moore, Sewickley, chairman; Henry Goodband, Sewickley, secretary.

CLEVELAND, O.: R. P. Brydon, chairman; Arthur Brown, secretary.

NORTH SHORE OF ILLINOIS: James A. Wilson, Lake Forest, chairman; John R. Clarke, Glencoe, secretary.

MONMOUTH & ELBERON, N. J.: Thomas W. Head, Red Bank, chairman; Frank T. Edington, Red Bank, secretary.

NORTH FLORIDA: Herbert Tickner, Orange Park, chairman; Alfred Addor, Jacksonville, secretary.

WESTERN PENNSYLVANIA BRANCH

The first annual meeting of the above branch was held in the Carnegie Library, Pittsburgh, on Tuesday, October 16, Manus Curran, chairman, presiding. Mr. Curran in a few well-chosen words thanked the local convention committees for their whole-hearted support both before and during the convention. John Barnet read several letters he had received from visiting members who attended the convention, which seemed to indicate they all had enjoyed their visit here. The applications of Carlos E. Norton for active membership and Walter L. Voss for associate membership were endorsed by this branch. A letter was read from James A. Wilson, chairman of the North Shore of Illinois Branch, asking this branch for an opinion on Article III, Section 1 of the By-laws, referring to members in arrears for dues. The national secretary has suggested to accept members in arrears as new members, endorsed by branches, subject to the approval of the association's meeting in March, when it may be proposed to suspend Article III until the next convention, at which time it may be acted upon. After considerable discussion, it was unanimously agreed by this branch to heartily endorse Mr. Ebel's suggestion, and the secretary was instructed to notify all branches of our stand on this subject. This branch heartily agreed with James Wilson, that there ought to be some system of co-operation between the branches so that any problem taken up by one could be taken up by all and thrashed out before the annual convention, when each branch would know where the other branches stood.

James Moore, superintendent of West Park, Pittsburgh, was unanimously elected chairman, and Henry Goodband, re-elected secretary-treasurer for the ensuing year. Manus Curran, the retiring chairman, was given a rising vote of thanks for the able manner in which he has presided over the meetings during the past year. The secretary read a statement of receipts, dues and expenses for the year ending October 16, showing this branch to be in a strong financial position. The report was approved as read. The next meeting will be a business and social meeting in charge of the following committee: John Fornoff, chairman; Wm. Thompson, John Barnet, R. W. Ross and James Moore.

It was agreed that future meetings shall be called at the pleasure of the chair.

HENRY GOODBAND, Secy.

THE NORTH FLORIDA BRANCH

Owing to an early cold spell, the coldest in twenty-eight years, the gardeners were kept very busy on the date of the last branch meeting, October 19, so that there was not the usual good attendance. The committee appointed to investigate the advisability of making an exhibit at the Florida State Fair in November, reported that the time was too short, that all the space had been taken, and that it is necessary to make an application for space two months in advance. It was voted that the branch apply for space for an exhibit at the Fair next year in ample time. Following the routine business and a general discussion, the meeting was adjourned, to meet again on November 16, at the home of J. K. Brower.

ALFRED ADDOR, Secy.

THE MONMOUTH CO. & ELBERON, N. J. BRANCH

A meeting of this branch was held in the rooms of the Monmouth County Horticultural Society at the hour preceding the October meeting of that society, to receive the report of the annual convention of the association. After listening to the report, submitted by Thomas W. Head, most of the members present declared that they wished they could have attended the convention. Secretary Edington of the branch was unable to be present at this meeting owing to illness. Another meeting will be held the latter part of this month to discuss the subject of payment of back dues before delinquent members can be reinstated. This subject is to be brought up at the Cleveland meeting in March, 1924, for consideration before the association as a body.

NASSAU CO. L. I. BRANCH

The annual meeting of the Nassau County, L. I., branch will be held the latter part of this month to elect officers for the ensuing year and to pass on several communications received from other branches. Several prominent members of the association from other sections are expected to attend and address the meeting. An invitation will be extended to all interested in the activities of the association, whether members or not, to be present.

JOHN R. McCULLOCH, Secy.

NORTH SHORE OF ILLINOIS BRANCH

The fourth meeting of the above branch was held at the secretary's home on the estate of James Simpson of Glencoe. Eleven members were present, with James Wilson in the chair. Several letters from branches in different states were read with reference to reinstatement of old members and Article III of the By-laws.

It was decided to send a delegate from this branch to Cleveland in March to give its views on the subject. Thomas Blair obtained his employer, Mrs. Kuppenheimer, as a sustaining member of the association.

The branch is investigating several new members who have shown their willingness to join by January 1, 1924. The next meeting of this branch will be held at the home of Wm. Michie on the John T. Pirie Estate, Lake Forest, November 15.

J. R. CLARKE, Secy.

AMONG THE GARDENERS

Charles Miller resigned his position as gardener to Mrs. R. S. Barnes, Washington, Conn., to accept a similar position with J. H. Harding, Red Bank, N. J.

Frank Black accepted the position of gardener in charge of the grounds of the New York Orphanage at Hastings-on-Hudson, N. Y.

John Johnson, seven years gardener to Mrs. J. A. Spoor, Blythwood, Pittsfield, Mass., accepted the position of superintendent of "Holmewood," the estate of Mrs. Raymond T. Baker, Lenox, Mass., succeeding E. J. Norman, who retires after thirty-three years in charge.

Thomas Evans, late superintendent to W. V. Kelley, Lake Forest, Ill., has accepted the position of superintendent to F. A. Rehm, Lake Geneva, Wis.

NEW MEMBERS

Sustaining: Van S. Merle-Smith, Oyster Bay, L. I. (Peter Morrison, gardener), and Mrs. Belle Kuppenheimer, Lake Forest, Ill. (Thomas Blair, gardener), Mrs. W. A. Roebing, Trenton, N. J.

Active: Martin Mattison, New York, N. Y.; Carlos E. Norton, Sewickley, Pa.; James A. Mackie, Narragansett Pier, R. I.; W. J. Peattie, New York, N. Y.

Associate: Walter L. Voss, Erie, Pa.

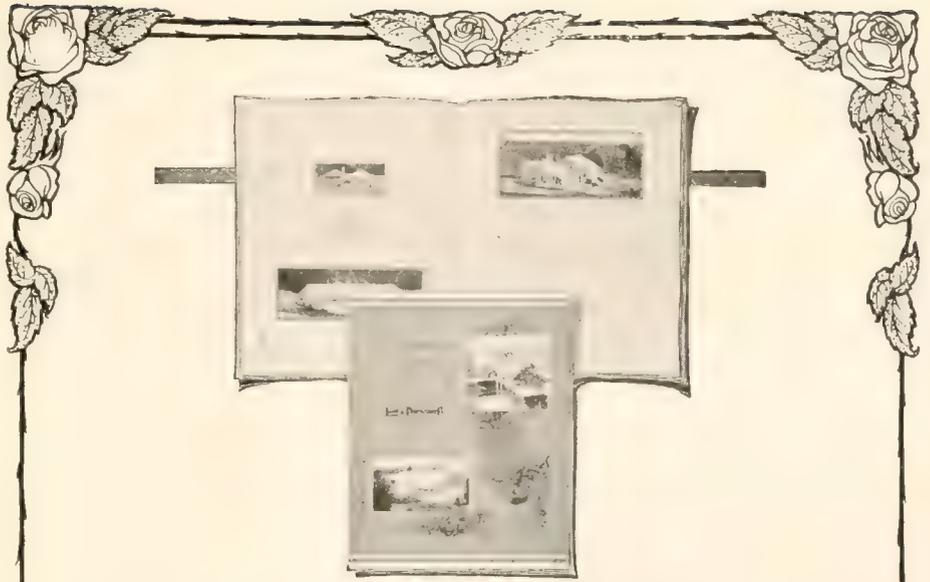

LOCAL SOCIETIES

EXHIBITION OF THE HORTICULTURAL SOCIETY OF NEW YORK

The annual Fall exhibition of the Horticultural Society of New York, which was held in the Museum of Natural History, November 8 to 11, inclusive, was beyond argument, we think, the best in the history of this society. The entries in the aggregate were numerous, and those in each class in nearly all cases sufficient in number to make competition keen, and to render it far more difficult to carry off a prize in any class, than in years when at this Autumn exhibition the entries in many classes were fewer. On this account the honor to those to whom prizes were awarded was the greater. Another important factor in this exhibition was the high quality in general of the entries.

Entering the foyer of the building our attention was at once drawn to its bordering of fine specimens of named Evergreens in great variety shown in tubs by Bobbink & Atkins. These formed a most happy setting for the blooming plants and cut flowers with which the foyer was filled.

There was a considerable number of specimen Chrysanthemum bush plants, not so many standards, and only a few grown in odd shapes, but keener competition in the twelve, and six eight-inch pot classes. In many of these plants we noted a departure from the growing of a very large number of rather small flowers to a plant and the growing instead of a smaller number of larger and better flowers to a plant, and we observed that it was these latter plants which

Of Special Interest To You Who Are Would-Be Greenhouse Possessors

With greenhouses, as with autos and most other things, there are a certain few that are favorites.

Year after year those same favorites have continued to be favorites.

Such being the case, then, there must be certain very logical reasons for it.

Reasons that will appeal to you quite as they have to others.

Appreciating such, it's a wonder we hadn't thought long ago to bring these favorite greenhouses together and make a special little catalog of them.

However, we have done it now. Done it in a most attractive way

that we are sure will appeal to you and your love of flowers and growing things.

Five favorites are shown, among which unless we are greatly mistaken, you will find just the greenhouse that best suits your needs and fits your pocketbook.

There are plenty of photos of both exteriors and interiors, besides plans and ample description.

So complete is it, that without any further ado, houses have been purchased directly from it. Mayhap you will do the same.

You are most welcome to a copy of this new Glass Garden Catalog.

		Chicago Cont. Bk. Bldg.
		Boston-11 Little Bldg.

carried off the first prizes in all the above-mentioned classes. A bush plant of what appeared to us as Well's Late Pink, and in the odd shapes a chair done in the species indicum were each in its way excellent.

There was keen competition in the class for "vases of one or more varieties arranged with foliage," but the flowers so shown, kept, we noted, poorest of all, though when first staged they were beautiful and imposing features. Long stems carrying the flowers high above the water, we suppose was the cause of their withering. This class, however, brought out much artistic talent in arrangement. Not many were able to fill the bill for the class of eighteen-inch stems, ten vases, ten varieties, three of each, but the class for five vases, five varieties,

three blooms of each, had more entries. The prizes in each were carried off by fine blooms.

The winners in the collection of twelve varieties and that of six staged excellent blooms. The classes of collection of singles in twelve varieties and in six varieties, and those of pompons in the same numbers with five terminal sprays to a vase, having not less than five flowers to a spray, had many entries and the blooms shown in each were admirable, being of a very high quality.

The vases of singles and of pompons arranged for effect made most attractive exhibits, the blooms lending themselves well to this use. The winners in the class for collection of anemones, six varieties, three blooms of each, exhibited some excellent

flowers of this less seen type of Chrysanthemum. The prize-winning exhibitions in the class for a group of cut flowers arranged for effect with foliage and covering one hundred square feet were composed of a variety of Chrysanthemum blooms arranged with red oak foliage; these were one of the large imposing features of the show.

The blooms shown by the prize winners, Chas. H. Totty Co., in the classes calling for a collection of twenty varieties and for ten vases, ten varieties, three blooms of each, classes in which not many even of the commercial growers can fill the requirements, were fine specimens of what our commercial growers produce. In the classes calling for collections of twelve varieties of pompons and for twelve varieties of singles exquisitely beautiful blooms were shown by Chas. H. Totty Co. and F. R. Pierson. The Silver Medal winning collection of seven varieties of pompons shown by the Cromwell Gardens was indeed a gem. A blush white pompon seedling of the large flowered type brought honorable mention to John Lewis Child Seed Co., consolidated with Edward T. Broomfield Co.

Passing from the Chrysanthemums and coming to the Roses shown by both commercial and non-commercial growers we felt that we were in a Rose show and not a general exhibition of plants and flowers. The non-commercial exhibitors merely never staged finer blooms. In these exhibits we noted several of the newer varieties, such as Souv. Claudius Pernet and America.

In the new varieties of Roses, we had an opportunity to see a new dark red, silver medal-winning sensation of the Charles H. Totty Co.; the prize-winning Souv. Claudius Pernet exhibited by this company and by L. B. Coddington; the brilliant bright red Rose Templar, shown by A. N. Pierson Co., which drew a certificate of merit; Mrs. Warren G. Harding, exhibited by Chas. H. Totty Co., and the well arranged group of ten vases of Mrs. Calvin Coolidge, shown by F. R. Pierson. In the older varieties we noted the prize-winning Double White Killarney, Key, Butterfly, Premier, Columbia, and American Beauty.

The Carnations were well represented in each class by both the well-known standard and the newer varieties, the blooms being of a higher quality than usual, making a very attractive display. The silver medal for a new meritorious variety, not in commerce, was awarded to a vase of unnamed large red blooms shown by J. Insley Blair.

The award for a group of greenhouse plants arranged for artistic effect and covering one hundred square feet went to a magnificent group, though the only one of Crotons, Dracænas, Ferns, etc., which was staged by William Boyce Thompson.

The Begonia classes drew groups of plants with elegant blooms of the Socotrana Hybrids, and the Lorraine type, which added greatly to the flowering plant features of the exhibition. F. R. Pierson, with a well-staged exhibit of splendid Ferns, varieties of Nephrolepis, and also several other species won the award for a collection of Ferns to cover one hundred square feet. There were splendid specimen plants shown of Cibotium Schiedeii, Adiantum, and Goniophlebium.

The high spot in this entire exhibition, excellent as indeed the other features were, the Chrysanthemums, the Roses, the Carnations, and the foliage plants, was the Orchids. So many and so large were the exhibits of Orchids that they occupied a space which reached half way around the border of the enclosed oval space in the foyer. A Brasso-Cattleya, named Admiral Jellicoe, in the prize-winning collection of twenty Hybrids of Arthur N. Cooley was awarded the sweepstake for the best variety, and Julius Roehrs Co.'s elegant collection of twenty

LUTTON QUALITY GREENHOUSES

*Patented by Wm. H. Lutton, Philadelphia, Pennsylvania
Manufactured by the Lutton Greenhouse Co., Philadelphia, Pennsylvania*

As Good As They Look!

NO gardener ever goes wrong in recommending LUTTON when a durable, sanitary and really artistic greenhouse is desired. And the cost for the unexcelled Lutton Patented V-Bar Quality Greenhouse is no greater, in the long run, than for the common, ordinary type of greenhouse. It pays 100% dividends in lasting satisfaction, the pride of its owner, and the ease with which it can be maintained.

Scientific, efficient heating system assures even temperature on coldest nights. Perfect ventilation—extra high headroom, providing space for tall plants on side benches.

Very easy to take care of—no trouble, no repairs, no worry. Maximum production at lowest cost.

An exclusive feature is its indestructible sanitary type of plant benches with galvanized iron frame, porous tile bottoms and slate retaining sides. No other greenhouse can have the V-Bar construction, as it is patented.

Write or call for further details, photos and evidence of superiority

WM. H. LUTTON COMPANY
260 Kearney Avenue, Jersey City, N. J.

Cattleyas Hybrids was also a winner. A Brasso-Cattleya, shown by Clement Moore, won the silver medal for a new meritorious variety not in commerce. Lager & Hurrell were awarded first for their collection of twenty-five species and varieties covering fifty square feet. The Clement Moore gold medal for one Brasso-Cattleya went to F. Eugene Dixon for "Eleanor Rice." In the six plants, six varieties class, Julius Roehrs Co., with several kinds of Orchids, and George E. Baldwin, with Cattleyas and Hybrid-Cattleyas, were the winners, and Col. H. H. Rogers and Lager & Hurrell in the three plants, three varieties class. There were several special exhibits not provided for in the schedule to which special prizes were awarded, namely, for an exhibit of Cypripedium plants to Mrs. E. E. Smathers, covering thirty square feet; for a most interesting collection of Cactaceous and Succu-

lent plants, a silver medal to W. A. Manda; for a well-staged exhibition of Cypripedium Sanderæ plants, one of the gems of the exhibition, a special award to Joseph A. Manda Co.; for a group of Cyclamen plants a special to Carl Grobba Mimlico, Ontario, Canada.

The displays of vegetables were numerous in nearly all classes, and considering the drought of the last Summer, excellent, but we noted that many of these came from Long Island, which they say is never "dry"; to Mrs. Herbert L. Pratt was awarded the Grand Sweepstake prize, the society's silver cup, for the best exhibition in the show, and it was most assuredly a meritorious exhibit.

In the Chrysanthemum classes, the awards were as follows:

Specimen bushes, first prize, Pembroke Estate, J. McMann, gardener; second

prize, William Boyce Thompson, Samuel McClain, gardener. Specimen standards, first, Pembroke Estate; second, Mrs. Herbert L. Pratt, James McCarthy, gardener. Twelve plants in variety, first Pembroke Estate; second, Samuel Untermyer. Six plants in variety, first, Col. H. H. Rogers; second, Pembroke Estate. Vase of one or more varieties, first, Mrs. H. M. Tilford, Joseph Tansey, gardener; second, Mrs. W. Redmond Cross. Ten vases in ten varieties, three blooms each, 18-inch stems, first, Mrs. Payne Whitney, George Ferguson, gardener. Five vases in five varieties, three blooms each, first, W. R. Coe, Robert Marshall, gardener; second, Samuel Untermyer. Collection of twelve varieties, one of each, first, William B. Thompson; second, J. Insley Blair, David Miller, gardener. For collection of singles and pompons, Mrs. Payne Whitney, Mrs. Paul Moore, Donald Crighton, gardener; Mrs. Herbert L. Pratt, Mrs. John T. Pratt, John Everett, gardener; and Mrs. H. M. Tilford were the successful contestants. Group of cut blooms arranged for effect, covering 100 square feet, any foliage, first Mrs. Payne Whitney, and, second, Otto H. Kahn, S. C. Horn, gardener.

In the Rose classes, for eighteen white, first, J. Insley Blair; second, Joseph P. Day, William Fowkes, gardener. Eighteen red first, Mrs. H. M. Tilford; second, J. Insley Blair. Eighteen pink, Columbia shade, first, W. R. Coe; second, J. Insley Blair. Eighteen light pink, Ophelia shade, first, Mrs. F. A. Constable, James Stuart, gardener; second, Mrs. H. M. Tilford. Eighteen dark pink, Premier shade, first, Joseph P. Day; second, Mrs. H. M. Tilford. Eighteen yellow, first, Mrs. Roswell Eldridge; second, Countess Mildred Holstein. Vase of fifty assorted, arranged for effect, first, W. R. Coe; second, Mrs. H. M. Tilford.

In the classes for Carnations, Mrs. H. M. Tilford led, carrying off all the first honors.

William Boyce Thompson won first prize for a group of greenhouse plants arranged for artistic effect to occupy one hundred square feet. Samuel Untermyer won first, and Mrs. Harold I. Pratt, second, for a collection of Fall fruiting shrubs and trees, cut branches, arranged for effect.

In the display of Begonias, tuberous-rooted, twelve plants, Mrs. Whitelaw Reid, E. Beckett, gardener, won first; J. Insley Blair, second. In the display of Begonias, Gloire de Lorraine type, twelve plants, William B. Thompson won first.

In the vegetable classes, Mrs. Herbert L. Pratt led all competitors, winning first for the collection of not less than 30 kinds, arranged for effect, and also first for the collection of not less than 15 kinds, while she was equally successful in the smaller classes. Mrs. H. M. Tilford won first for white and black grapes, grown under glass.

TARRYTOWN, N. Y. FLOWER SHOW

The twenty-fifth annual floral exhibition of the Tarrytown Horticultural Society was held in the Y. M. C. A. building October 31, November 1, and 2, 1923. Although the hall was somewhat smaller than Music Hall, where the exhibitions have been held heretofore, it was beautifully decorated with Southern Smilax and was one bouquet of flowers. The exhibits were particularly fine throughout. Three magnificent groups of Chrysanthemums, filling the south end of the hall, attracted a great deal of attention. The competition on these was very close and the judges had difficulty in deciding. The exhibits were made by Mrs. Frederic E. Lewis, John D. Rckefeller and Mrs. H. M. Tilford.

The other special feature of the exhibition was a fine table of the new yellow rose, Mrs. Calvin Coolidge, exhibited by F. R.

Pierson, which was awarded the society's Silver Medal, also a Certificate of Merit.

One other fine exhibit was made by Mrs. Arthur Curtiss James, which was an exhibition of fibrous-rooted Begonias, and was one of the finest exhibits that has ever been placed on the exhibition tables. It was awarded the society's Silver Medal and Cultural Certificate.

The largest bloom of the show was taken from the exhibit of Mrs. Frederic E. Lewis. The quality of the Chrysanthemums and Roses and Carnations was particularly fine, really better than has been shown in other years.

In the Chrysanthemum classes the winners were as follows: 18 blooms of anemone flowered, first, Mrs. E. E. Smathers, W. D. Robertson, gardener; second, Mrs. E. Myers, Jr., Charles Ruthven, gardener; 18 blooms, 6 varieties, 3 of each, first, Mrs. F. E. Lewis, J. W. Smith, gardener; second, Mrs. E. E. Smathers; 12 blooms, distinct varieties, first, J. Insley Blair, David Miller, gardener; second, Mrs. G. E. Lewis; 6 blooms, distinct varieties, first, H. Sidenberg, Alexander Anderson, gardener; second, Richard Colt, John MacIntyre, gardener; most effectively arranged vase, first, Mrs. H. M. Tilford, Joseph Tansey, gardener; second, William Mitchell, R. Ponce, gardener; largest bloom, Mrs. F. E. Lewis; best 3 blooms, first, Col. H. H. Rogers; second, George F. Baker, William Ellings, gardener; 12 blooms, 4 varieties, first, Col. H. H. Rogers; second, Richard C. Colt; 20 blooms, 5 varieties, first, Mrs. F. E. Lewis; second, Mrs. H. M. Tilford; 12 vases of singles, first, Mrs. E. Meyer, Jr.; second, Mrs. E. E. Smathers; 6 vases of singles, first, George F. Baker; second, Col. H. H. Rogers; best collection of singles, first, Mrs. H. M. Tilford; second, Mrs. E. E. Smathers; 8 vases of pompons, first, Mrs. E. Meyer, Jr.; second, Mrs. H. M. Tilford; best display of cut blooms, covering space of 80 square feet, Mrs. H. M. Tilford, first; Mrs. E. E. Lewis, second.

In the vegetable classes Mrs. Jesse I. Straus, Fred Sparks, gardener, carried off the honors.

The Rose classes were closely contested by J. Insley Blair, and Mrs. F. E. Lewis.

In Carnations, Mrs. H. M. Tilford and George F. Baker were leaders.

Dr. Joseph Blake, Thomas Wilson, gardener, won first prize with the table decoration, and Mrs. J. S. Halle, John Watts, gardener, second.

THE MORRIS CO. N. J., SHOW

The Morris County, N. J., show, the twenty-seventh annual, held in the armory of Morris County at Morristown, N. J., on November 1 and 2, was a pronounced success, for which the shows of the Morris County Gardeners' and Florists' Club are noted, both in point of quality, arrangement and attendance. It was a very attractive exhibit in every respect.

lence Cup was won by L. L. Dunham, E. Wild, gardener. A Silver Cup was awarded to Mrs. Twombly, Robert Tyson, gardener, for a magnificent group of Chrysanthemums arranged with foliage plants in the center of the hall.

It would be difficult to find more perfect blooms of Chrysanthemums than were to be seen at this show. Joseph P. Day, William R. Fowkes, gardener, was awarded a silver cup for 24 marvelous blooms in 4 varieties. For 15 blooms, 5 varieties, Mrs. T. Fuld, William McIntosh, gardener, won first, and Mrs. H. McK. Twombly scored with 12 blooms, distinct varieties. Otto Koch, gardener of the Morris County Asylum, exhibited a splendid collection of palms, ferns, and other foliage plants and also some fine 'Mums. Mrs. Paul Moore, Donald Crighton, gardener, won first prize with a vase of excellent Japanese singles, and pompons, and also a vase of splendid singles. Other winners in the Chrysanthemum classes were Mrs. J. O. H. Pitney, Charles Fleisch, gardener, and the Dickson estate, F. Breese, gardener. Among the commercial growers, Charles H. Totty Co. was the only exhibitor but not for competition. In the group class for Chrysanthemum plants only, L. L. Dunham won first; Mrs. Paul Moore, second.

In Roses, Mrs. Twombly, Mr. Day and Mr. Dunham shared honors about equally. Charles H. Totty Co. made a splendid showing arranged for effect. David Frances won honors for a basket of "Butterfly" Roses.

In Carnations, Mr. Dunham and Henry Young, W. R. Seymour, gardener, led with excellent blooms.

Mr. Dunham also exhibited some fine 'Mums in pots, winning with 6 plants, single stems; 12 bush plants, and 6 single plants, all well grown. He also exhibited 12 plants, raised as standards, all testifying to the ability of his gardener, E. Wild, as a grower of 'Mums.

Mrs. H. McK. Twombly had a very fine exhibit of large flowered Begonias which received a special prize. A special prize was also awarded to Otto H. Kahn for his display of foliage plants and 'Mums.

Honors for table decorations went to Mrs. Ridley Watts, Samuel Golding, gardener.

UNUSUAL SPRING FLOWERS

In my border in early May there is no flower so much admired as *Camassia Cusickii*. The tall spike springing from a cluster of lily-like leaves is often two feet high. The pale blue six-pointed, rather large flowers, arranged loosely on the stalk, begin to bloom from the bottom upwards, so that their blooming period lasts several weeks. If they are picked they come out in water and last a long time. The bulb looks like the elongated beet root and in a few years makes large clumps that can be highly rated as soon as the leaves die down which is a few weeks after blooming. We have a native *Camassia* variety, *Fraseri*, commonly known as the White Hyacinth, or Indiana Quamash. It is quite small in comparison with *Camassia Cusickii*. It requires no special care to grow them; they are quite hardy and thrive in the same soil as Lily bulbs. Plant them deep, from six to eight inches, and leave them undisturbed, unless you wish to separate them to make other clumps in your garden. It well deserves to be more widely cultivated.

We all know Snowdrops; but how many of us know Snowflakes? Its leaves are just like the Narcissus with a tall stalk surmounted by a pure white drooping blossom, each petal tipped with bright green. I first saw it in a Kentucky garden, and brought for

it; but, not knowing the botanical name I could not order it from a nurseryman, when, lo and behold! one fine spring morning I found one blooming in my garden. I was sure at first the fairies had planted it, but in practical reasoning I decided it must have been a present from my kind nurseryman, sent with a lot of bulbs ordered the Fall before. So, garden-lovers, do not forget *Leucojum vernum*, the Spring Snowflake. *Farm and Garden*.

STATEMENT OF THE OWNERSHIP, MANAGEMENT, CIRCULATION, ETC., required by the Act of Congress of August 24, 1912, of "Gardeners' Chronicle of America," published monthly at New York, N. Y., on October 1, 1923

State of New Jersey }
County of Union } ss.

Before me, a notary public in and for the State and county aforesaid, personally appeared M. C. Ebel, who, having been duly sworn according to law, deposes and says that he is the editor of the "Gardeners' Chronicle of America" and that the following is to the best of his knowledge and belief a true statement of the ownership, management (and, if a daily paper, the circulation), etc., of the aforesaid publication for the date shown in the above caption, required by the Act of August 24, 1912, embodied in section 443, Postal Laws and Regulations, printed on the reverse of this form, to wit:

1. That the names and addresses of the publisher, managing editor, and business manager are: Publisher, The Chronicle Press, Inc., 286 Fifth Ave., New York, N. Y. Editor, M. C. Ebel, 286 Fifth Ave., New York, N. Y. Managing Editor, M. C. Ebel, 286 Fifth Ave., New York, N. Y. Business Manager, D. Ebel, 286 Fifth Ave., New York, N. Y.

2. That the owners are (give names and addresses of individual owners, or, if a corporation, give its name and the names and addresses of stockholders owning or holding 1 per cent, or more of the total amount of stock).

The Chronicle Press, Inc., 286 Fifth Ave., New York, N. Y. M. C. Ebel, Summit, N. J. M. E. Burniston and J. A. Burniston, both of Madison, N. J. S. Warendorff, 325 Fifth Ave., N. Y. Chas. H. Totty, Madison, N. J. A. Bauer, Deal, N. J. J. Barnett, Sewickley, Pa.

3. That the known bondholders, mortgagees, and other security holders owning or holding 1 per cent, or more of total amount of bonds, mortgages, or other securities, are: (If there are none, so state.) There are no bondholders, mortgagees or other security holders.

4. That the two paragraphs next above, giving the names of the owners, stockholders, and security holders, if any, contain not only the owners, stockholders and security holders as they appear upon the books of the company, but also, in cases where the stockholder or security holder appears upon the books of the company as trustee or in any other fiduciary relation, the name of the person or corporation for whom such trustee is acting, is given; also that the said two paragraphs contain statements embracing affiant's knowledge and belief as to the circumstances and conditions under which stockholders and security holders who do not appear upon the books of the company as trustees, hold stock and securities in a capacity other than that of a bona fide owner; and this affiant has no reason to believe that any other persons, association, or corporation has any interest, direct or indirect, in the said stock, bonds, or other securities, than as so stated by him.

Sworn to and subscribed before me this 4th day of October, 1923.

M. C. EBEL, Editor.

THE SUMACHS

For a colorful Autumn landscape we know of no other genus that offers more desirable subjects for this purpose than the Sumach (*Rhus*), writes Samuel Newman Baxter in the *Florists' Exchange*. It would seem that all the members of this family vie with each other for supremacy in coloring which runs from shades of yellow and orange into brightest crimson. For the small home grounds, perhaps the most desirable is the Smoke Tree, Mist Shrub, or Purple Fringe (*Rhus cotinus* in most nursery catalogues although it is now also referred to as *Cotinus Coggygria*). The common names aptly describe this old garden favorite and refer to the fluffy fruiting panicle in June and July. The oval leaves are unlike most Sumachs.

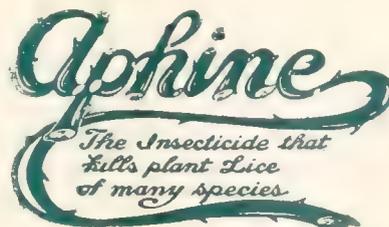

For the larger estates or in parks where a "wild" effect is wanted, the Stag's horn Sumach (*R. typhina*) and Smooth Sumach (*R. glabra*) are most in demand, followed by the Shining Sumach (*R. copallina*). All of these have the typical pinnate leaves, though the stems are "winged" between the leaflets on the Shining Sumach. The Stag's horn Sumach is the tall growing one with fuzzy stems and the *R. glabra* its dwarf counterpart with smooth stems. The last two named have also cut-leaved varieties which are interesting because of the lacy

nature of the foliage. The crimson seed cones are also an attractive feature of these Sumachs and are best appreciated as seen from above where we may obtain the benefit of the foil of fern-like foliage.

Next in popularity with the landscape men especially is the Fragrant Sumach (*R. aromatica*) so named because of the fragrant aromatic odor of the foliage when bruised. This is an ideal plant for foreground planting in the natural landscape, its slightly ascending yet horizontal branches being just suited for this position, and when colored in Autumn, resemble a flame licking the ground. We do not recommend it for the small show place but for park planting it is invaluable.

For an unusual single specimen we should suggest *R. Osbeckii* or *Javanica*, which we have not seen for some time.

All these, and others which we might enumerate are noteworthy for their Autumnal colored foliage. Yes, even the despised Poison Ivy (*R. toxicodendron*) brightens the Autumn landscape. The Sumachs may be propagated by hardwood cuttings, seed or root cuttings, the latter method being evident from the manner in which new plants will spring up in a block where the old plants have been removed, each piece of root which is allowed to remain, providing new plants.

The Insecticide of Recognized Merit for Greenhouse and Garden

APHINE is a concentrated material—mixes readily in water—efficient in its action—easily applied—free of the disagreeable odors and features of most insecticides—excellent as a wash for decorative plants.

FOR THE GARDEN—As a remedy against all sap sucking insects infesting flowers, fruits and vegetables, APHINE is most effective.

FOR THE GREENHOUSE—Applied at regular intervals (once each week or ten days) APHINE will keep plants in the greenhouse and conservatory free of insect pests.

FUNGINE—For mildew, rust and other blights affecting flowers, fruits and vegetables.

VERMINE—For worms and insects infesting the soil.

A view of the Edward F. Hutton Estate, Roslyn, L. I.

The Tribute of Andrew Johnson to Davey Tree Surgery

Roslyn, L. I., August 28, 1923.

THE DAVEY TREE EXPERT COMPANY, KENT, OHIO.

Dear Sirs:

Your men have just recently completed work on some of our trees. This service, as usual with your Company, was very satisfactory.

I understand that your Long Island representative is sending you a picture of our large white oak. This tree, a few years ago, when Mr. Hutton bought the place, was in a dying condition. It was carefully pruned and treated by your men at that time to restore its structural strength, and then it was nourished under the direction of your men, and today, as the picture will show, is in perfect health, a living monument to the success of tree surgery. Sincerely yours,

ANDREW JOHNSON,

Superintendent of Mr. Edward F. Hutton's Estate, Roslyn, L. I.

To save fine old trees, every gardner and estate superintendent needs highly skilled assistance. Many, like Mr. Johnson, protect their trees by Davey Tree Surgery—a science developed by a generation of study and experience. A careful examination of your trees will be made by appointment.

THE DAVEY TREE EXPERT CO., INC., 311 Elm Street, Kent, Ohio.

Branch Offices: Boston, 100 State St.; New York, 100 Broadway; Philadelphia, 100 Arch St.; Pittsburgh, 331 Fourth Ave.; Buffalo, 110 Franklin St.; Cleveland, Hippodrome Bldg.; Detroit, General Motors Bldg.; Cincinnati, Mercantile Library Bldg.; Chicago, Westminster Bldg.; St. Louis, Arcade Bldg.; Kansas City, Seavitt Bldg.; Los Angeles, Garland Bldg.; Montreal, 252 LaGauchetiere, West.

Davey Tree Surgeons are near you—if you live between Boston and Kansas City, or in California. Write or wire nearest office for a list of branches or for the nearest cost of operation.

JERSEY'S BEAUTY—The Greatest Dahlia Under Cultivation

Originated by W. H. Waite, Superintendent for E. D. Adams, Esq., Rumson, N. J.

A REAL pink Decorative of exquisite shading; a soft pastel, translucent pink of intense richness. Large deep blooms of perfect form on extra long, stiff stems, and of extraordinary keeping qualities. The graceful form of the flower with the long outer petals curving back to stem, is as pleasing as it is artistic. Altogether, a floral creation of lasting charm.

Has Gold Medals, Certificates, First Prizes, and other high honors to its credit. "Jersey's Beauty" scores highest of any Dahlia at the Trial Gardens of the American Dahlia Society, being awarded 91 points for perfection and merit, grown in company with the World's Best Dahlias. "Jersey's Beauty" has succeeded exceedingly well everywhere, including in California.

It is important to make reservations now.

Don't Use the Wrong Name

Have you been embarrassed because you did not use the proper common or scientific name when buying or selling plants? It will never happen again if everybody owns and uses

STANDARDIZED PLANT NAMES

The New Plant Check-List

Lunatic plants-men have put eight years of gratuitous work on this book. There are 40,000 entries in one carefully cross-indexed, alphabetical list that covers 546 pages. All plants introduced to American horticulture to as late as January, 1923, are listed, including the varietal names of the rose, iris, apple, and similar groups. The best common and scientific name for each has been adopted for general use. The name you know a plant by is there—you can see at a glance whether or not it is correct.

Hon. Henry Wallace, Secretary, U. S. Department of Agriculture, says, "It should make possible a new era in the make-up and usefulness of American nursery catalogs."

Peter Bissett, Plant Introducer, U. S. Department of Agriculture, says, "This will undoubtedly be very helpful to me in my work in this office."

Standardized Plant Names is published in two editions; the standard edition, blue cloth binding at \$5, postpaid; the pocket edition on thin India paper with limp covers at \$6.50, postpaid. Send your order to

Helps To Better Gardens

Soil, season, and sunshine are essentials, but by far the greatest factor in the garden is the seeds, bulbs, and plants you entrust to the soil.

For 86 years the House of Dreer has been governed by but one motive: to supply the choicest seeds, plants and bulbs that human ability can produce. America and Europe alike contribute to make Dreer's a vast supply house of horticultural merchandise and the index to it we offer in

DREER'S GARDEN BOOK

We have endeavored to make this book a true representative of our business. Experienced gardeners throughout the country have helped us make the cultural directions practical and readable.

Its 224 pages contain perhaps more practical garden lore than that found in many an expensive garden book. It matters little whether you are interested in vegetables, annuals, or perennials from seeds, choice Dahlias, Gladioli, or Cannas, flowers or house plants, you will find them all listed and offered in such a way as to make it easily possible for you to determine just what kind of a garden you want and may have.

This freely illustrated book, with hundreds of photographic reproductions besides eight full pages in colors, is gladly mailed free. Please write for your copy to-day, mentioning this publication.

Devoted to the Science of Floriculture and Horticulture

Vol. XXVII

DECEMBER, 1923

No. 12

THE FOOTPATH TO PEACE

To be glad of life, because it gives you the chance to love and to work and to play and to look up at the stars, to be satisfied with your possessions, but not contented with yourself until you have made the best of them, to despise nothing in the world except falsehood and meanness, and to fear nothing except cowardice; to be governed by your admirations rather than by your disgusts; to covet nothing that is your neighbor's except his kindness of heart and gentleness of manners; to think seldom of your enemies, often of your friends, and every day of Christ; and to spend as much time as you can, with body and spirit, in God's out-of-doors. These are little guide posts on the footpath of peace.

HENRY VAN DYKE.

Things and Thoughts of the Garden

WILLIAM N. CRAIG

THE great deficiency in precipitation, while it has by no means been wiped out in the Eastern states, has been relieved in some measure so that there is now less probability of evergreens, particularly broad leaved ones, suffering from dryness at the root. There are still, however, far too many amateurs and not a few practical gardeners who make a habit of mulching their rhododendrons heavily with leaves as soon as they fall from the trees. The intention is excellent but the leaves prevent the moisture from reaching the roots of the plants. By all means mulch, but remember that too early covering is very likely to prove injurious. It is a too common practice to cover beds of these handsome broad leaved evergreens with burlap as a winter protection which does far more harm than good, for even when plants look fresh and green when uncovered, a day or two's exposure with a hot sun focussing on them will speedily give them a sickly appearance. Windbreaks for rhododendrons are excellent, and if the plants are moist at the roots and well mulched with leaves they will winter vastly better than when covered overhead.

* * *

A superintendent on one of the large estates near Boston has very great faith in cocoa shells, which he obtains at one of the large nearby chocolate mills, as a mulch for rhododendrons and kalmias. He also makes use of them for bedding his herd of Guernsey cattle on, and claims that they are cleanly, absorb the liquids better than any other material, and that the manure with the addition of cocoa shells gives better results in the flower and vegetable garden than when other forms of bedding are used. That it is a neat form of bedding there can be no question and it would seem as though growers in other sections convenient to chocolate factories might do well to obtain a moderate supply and experiment with it. The price is low and should prove no

deterrent to anyone desirous of doing a little experimenting.

* * *

It is rather unusual to see ploughing in active progress in New England in December, although on one occasion I had some done in Christmas week. It is a wonderful asset to have the month of December mild. Not infrequently frost seals the ground right after Thanksgiving, in fact the most furious and destructive snowstorm I have experienced in America occurred on November 26, 1898. Our cousins across the ocean have a great advantage over us in being able to continue outdoor operations practically the whole Winter, which enables them to get all of their digging, ploughing, trenching, pruning and other operations completed ere Spring arrives. There is time to do the work more thoroughly than we, as a rule, are accustomed to do it here. There are still far too many even among our gardeners, to say nothing of amateurs, who fail to take advantage of these open early December days to complete work which is usually left until the over strenuous springtime.

* * *

A letter from a friend who is a good gardner and an excellent botanist, now located at Coco Grove near Miami, Florida, makes one wish to make a trip there to enjoy the glorious tropical vegetation. Ordinarily we think of Crotons, Pandanus, Acalyphas and other warm house plants, as mere pot plants and occasionally use them for sub-tropical bedding. Near Miami they are seen on all hands, immense bushes 15-25 feet across. In that balmy, frostless region Cocanut, Royal, and other palms in great numbers are 75-100 feet high, Ficus of almost unbelievable size, and Casuarina equisetifolia, the "beefwood tree" of Australia 100-110 feet high and not over 15 years old! The most remarkable growth, however, is that made by Mangoes, Avocados, and Paw-Paws in the

DEC 20 1923

nurseries of the United States Plant and Seed Introduction Station at Chapman Field. Planted out from 4-inch pots last May they are now 10-12 feet high and loaded with their delicious fruits. These are but a few of the many plants described as growing with a reckless abandon in Southern Florida, which makes it the greatest tropical paradise in the United States. It must be very pleasant to live amid such surroundings but methinks if I were located there for any lengthy period that the sight of a bed of our northern bulbs or perennials in Spring, or even a plant or two in bloom of Scotch heather, English primrose or any one of many North American native plants would to quote Harry Lauder "warm the cockles of ma hairt" as no tropical flowers could do.

* * *

Already the seed catalogues are coming to hand, and now that the nights are long and we must perforce, for various reasons, spend more time at home than has been our wont, is an admirable time to "read, mark, learn, and inwardly digest" them. There is a good deal of satisfaction to be derived from the careful study of a well arranged catalogue. We may know that the fulsome descriptions are often overdrawn, and are very willing to accept them "cum grano salis," especially when we remember that the bulk of catalogue writers are not practical men outside their own sphere, viz., the seed business. It is true that many novelties offered are not even the equal of existing standard varieties, but there are always some improvements to be found and anyone with even a small garden should be progressive enough to try two or three novelties each season. They may not all come up to our expectations, but if we get one really fine new thing we are well rewarded, and naturally feel doubly proud if our neighbors do not have it.

* * *

Among the very desirable yellow flowering annuals are the *Leptosynes*. Nearly all are natives of California and are closely allied to *Coreopsis*. The foliage more nearly resembles *Cosmos* than *Coreopsis*. We do not see very many of these annuals in our gardens, less than their merits would seem to warrant. While they may be sown outdoors like many of our most easily grown annuals, they will flower much better and earlier if started in a frame or greenhouse. I grew *L. maritima* for many years in pots for spring flowering. It carries its flowers on very long stems and the flowers are large and of a very pleasing soft yellow color. It is a very desirable annual for the greenhouse. *L. stillmani* is an improved variety introduced 25 years ago by Benary, the well known German seed firm. Both varieties make excellent pot plants, and outdoors they seem to thrive especially well in damp soil, although this is by no means necessary for their successful culture.

* * *

Those of us who had horticultural training in Europe will easily remember the beds of the common musk which were grown for the delicious fragrance of its foliage. It would seem as though in even the most humble cottage there was always to be found a pot of Musk, along with Geraniums, fancy or show Pelargoniums, Fuchsias, Calceolarias and blue Lobelias. The strange thing about this modest unassuming plant is its entire loss of fragrance in late years. The reason for this no one seems able to account for, and after making many inquiries from friends abroad, I have not received an encouraging reply from anyone; all admit that the one time odor has vanished mysteriously. Can it be brought back and retained by any process? When we think of the old musk, we instinctively associate fragrance with it, and without it the plant has but little horticultural value. For several years plants came up freely below the benches

of a greenhouse with me in Brookline, Mass., but none of them had any fragrance. Would artificial culture continued over a period of years be likely to rob this or other plants of fragrance? It seems uncertain when the odor vanished, and we are unlikely to get much desired information on this score.

* * *

Speaking of the common musk, I very well remember how popular the large flowered form *Mimulus moschatus harrisoni* was about 40 years ago and no doubt it is still in commerce. We used many thousands of it in carpet bedding in those days, a time when William Robinson, J. Simpson of Wortley Hall and other hardy plant advocates were hurling scorn and ridicule at carpet bedding and when they had but few agree with them. For bedding purposes in the north of Britain, Harrison's musk was amazingly popular, and it certainly was a great bloomer. There is another member of the *Mimulus* family, native also of California which years ago was prized as a cool greenhouse flowering plant, viz., *M. glutinosus*, called formerly *Diplacus glutinosus*. Once in a while I run across a few of these plants in old greenhouses. The flowers are buff or orange colored, and quite attractive, and there would seem to be a place today for this plant in cool greenhouses. It is shrubby habited and the foliage as its name would indicate is very sticky.

* * *

At Christmas, berried plants are always very popular. Amongst these are the scarlet and yellow fruited *Solanums*, or Jerusalem cherries, which are of very easy culture. Then there are the so called Christmas cherries, a variety of pepper, and the very pretty *Ardisias* which are of much slower growth and must in consequence command a fairly high price. In addition an increased number of the handsome dwarf Otaheite oranges are grown, but in these northern states we now miss the beautifully berried English hollies, *Skimmias*, and *Aucubas*, once freely imported but now debarred. As we cannot successfully and profitably grow these debarred plants here, what is there we *can* grow which will give us brightly berried plants of moderate size and be of comparatively easy culture. Would it not be possible to grow plants of some of the *Berberis* in pots plunged outdoors through the Summer which would make acceptable holiday plants? Some of the newer Chinese varieties fruit while very small and their fruits are handsome and of a brilliant color, I presume the thorns would be the main objection to the use of *Berberis*, but the foliage of holly is very prickly, and it should be remembered that some of the finest new *Berberis* are virtually evergreen.

* * *

The growing of large single stem chrysanthemum blooms has declined very much in America in late years and the pompons, anemones, and singles have advanced in favor tremendously. In France and Great Britain, on the other hand, the tendency would almost seem to have been the other way, judging by the reports of the great numbers of big blooms staged at the numerous exhibitions recently. The small flowered types are by no means ignored but their importance at shows and in the flower markets seems much smaller than here; this may be in some measure due to the fact that our European friends have a much longer season for the small flowered types outdoors than we do. They start to bloom much earlier there than here and the mild Winters make it easily possible to have outdoor flowers for three to four months. In looking over lists of the best early outdoor bloomers there, I am struck by the fact that the bulk of these do not succeed well here. Probably no two lists of hardy chrysanthemums here would agree, what would do well in

(Continued on page 297)

In the Garden and in the Greenhouse

GEORGE F. STEWART

IN THE GARDEN

WE have now arrived at the close of the year and the beginning of another. Some crops have come out about as we expected, while others have been disappointing. We are told that hope is the last thing in the world; certainly a gardener needs to be full of it, as his whole work depends on co-operation with Nature, and the greatest students of the elements are still very ignorant about its actions. Many of us, who are gardeners, have had little theoretical education, which makes us depend more on the practical and on what we may have picked up by reading and observation. When we have done our best with a crop and the result is more or less of a failure, it ought to bring out what is really in us by the way we take it, for it is easy to do gardening when everything is a success. Sometimes one may have an unreasonable employer (which makes it all the harder to bear a disappointment) who does not seem to be able to understand that gardening cannot be done wholly by rule; the powers of Nature are often too much for any rule man may lay down.

Late December, no matter how we feel its frosty chill, ought to make us glad, as no doubt it did those Judean shepherds when they found that the *Promised One* had arrived to bring deliverance to an oppressed humanity. No thinking man can deny that, with the advent of Christ, a force to be reckoned with for the uplift of humanity appeared on this earth, no matter what our private opinions of Him may be. Early January is here also. If I remember correctly the name of this month comes from a root which means a door. The door of opportunity is ahead of us another year, and now is the time to lay out our plans.

Work in the garden at this season is partly in seeing that the more tender plants have suitable protection against severe frost. If the covering is of leaves, or anything that the winds may blow away, a few branches laid over, will keep it in position. See that the raspberries which are in a location where they are liable to suffer, are well protected. The best way is to cover them with loam after they have been laid low on the ground. However, if this has been by any means neglected until the ground has frozen too hard, they may be tied up and protected with straw. Strawberries, as soon as the ground has frozen quite hard, may be covered with litter. This covering is to keep the plants frozen steadily through the Winter, not to keep them from freezing, so that a heavy covering does more harm than good.

Root crops and potatoes, as time permits, should be looked over and any that show signs of decay, removed.

As time and weather permits, the pruning of fruit trees may be attended to. Pruning is to keep the trees from becoming overcrowded with branches, to assist the formation of fruit buds, and also the preservation of their shape and symmetry. The trees also may be sprayed for scale if this has not already been done. It is advisable to give protection to the trunks of trees against the attacks of mice, which will very soon destroy a tree by girdling the bark; prevention is better than cure.

The lilacs are very liable to an attack by scale and a spray with an insecticide may be given as a preventative even if no scale is seen on the plants.

In localities where spinach remains through the Winter, a slight covering of hay will keep it from freezing and thawing. Of course, we all know that a blanket of snow

is the best covering for plants, but in some localities it comes and goes, making it necessary for us to provide other means of protection.

This is a good season of the year to look over the stock of stakes and bean poles, so that provision may now be made to make up for any shortage, as there is always plenty to do when the time arrives to use them next season. Tools, and flats for carrying and transplanting plants in the Spring may need to be repaired or replaced by new ones. If all these things are on hand, it saves time when the mind is occupied with more important things.

All plants that are in cold frames ought to be looked over regularly, removing any dead leaves from the plants; or if the plants, such as violets and pansies, are planted out, the soil should be stirred around them. If the sides of the frames are well banked with strawy horse manure, mats and shutters, it will keep out the frost. Take advantage of every mild sunny day and air them freely.

Watch the evergreens carefully, should there be heavy falls of snow, and remove the snow as soon as possible. It is easy to damage them in a way that cannot be remedied.

IN THE GREENHOUSE

Seeds of onions may be sown about the first of the year. These, if properly handled, may be used for exhibition next year. We have tried potting them off but have had better results by transplanting them in flats, allowing a good space between each plant.

Successional sowings of lettuce may be made and also of beans, spinach, cauliflower, radishes and parsley. Tomatoes, beans and cucumbers may be grown together in a night temperature of sixty degrees. Lettuce, radishes and cauliflower may be grown in a night temperature of forty-five degrees. Rhubarb may be forced in a temperature of from fifty-five to sixty; beets and carrots around sixty degrees.

Chicory roots should be forced in the dark, also turnip tops and beet tops which make excellent salads. It is all a question of space and time for the enjoyment of these vegetables in Winter. They are of much better quality than those which may be obtained in the open market, grown in the South during the Winter months. There is just as much enjoyment in growing vegetables as there is in growing fancy plants and flowers.

Late December and early January find the greenhouses probably as scarce of flowers as during any period of the year. I refer to cut flowers, for chrysanthemums are about past, which makes quite a difference in getting material to fill a good box of flowers for the use of the family several times a week. On the average place, probably the carnation and the rose are the principal stand-bys. Those who grew the carnations indoors during the Summer, and have looked after all details necessary to their growth, such as cleanliness and food, will see the advantage at this season. The plants will produce more flowers and have better stems than those which are planted out in the field for the greater part of the Summer.

Skillful growers of the rose can time an entire crop to come in at a given period, but in a small rose house, which is the general rule on private estates, this is not advisable. It is better to have one-half of the plant growing and the other half setting buds and flowering. This can be regulated to a certain extent by pinching some of the buds as soon as they set early in the Fall and allowing the others to proceed to flowering.

Begonias will now be in full flower and the temperature may be reduced to make the flowers firm up. They will continue in flower longer and have better lasting qualities. Watch the begonia leaf cuttings and as soon as the first break appears, pot them off in an open, porous soil.

If one has a large plant of *Asparagus sprengeri*, seeds will be ripening on it. These should be picked, cleaned, and sown right away. Fresh picked seed is more dependable than old seed for it germinates more evenly. The warmest corner of the greenhouse is the place for them, and they should be kept saturated with water and a pane of glass placed over the receptacle until they begin to germinate. Six to eight inch pans of this plant are useful for greenery.

Cyclamen seed that were sown in August will now have developed a few leaves. They may be potted in small pots and kept in a night temperature around sixty degrees. A position as near the glass as possible is the best place for them and a slight shade over them until they grip the soil in the pot when the sun is bright.

Carnation cuttings may be secured at this season. The growths that appear on the side of the flower stems make the best cuttings, forming plants that flower more continuously. They may be placed in sand in a night temperature of fifty degrees. Water them every day for the first ten days. It is necessary to shade them on bright days—cheese cloth makes an ideal shade—until they show signs of pushing out roots.

Rose cuttings may also be rooted now. Flower stems, cut with two eyes left on each piece, make better plants than blind wood. This is also true of wood used for grafting. I believe that if more care were given to the selection of wood for propagating purposes there would be no trouble about the deterioration of varieties.

Many years ago *Deutzia gracilis* was more commonly used for forcing than we have seen it lately. I remember when a boy, it was pot grown for this purpose entirely. Cuttings were taken in January and pinched until six or seven breaks were secured. I recall one gardener who used to grow them in his warmest grape house, until they were about two feet high, and then gradually hardened them off until they could stand the full sunshine. He finished them up outdoors and gave them a good freezing. He used to flower every shoot in fine shape in six-inch pots the following Winter, taking them in in batches.

This is the time of the year to secure cuttings for large bush *Chrysanthemums*. Root them as quickly as possible in an intermediate temperature, that is between fifty-five and sixty degrees, and pot them along as they require it in a strong, well fertilized loam. Root the cuttings close to the glass in the full sunshine, watering them twice a day for the first ten days. When I wrote watering, I should have written flooding. If this is done there will be no danger of damping off, and any wilting they will do will not harm them. By the time they dry out, after the ten days mentioned above, they will be rooted.

Keep the *Dipladenias* on the dry side until the end of January. Once a week will be often enough to water them, and have them in a night temperature close to forty-five degrees and exposed to the full sunshine all day. These plants start much stronger and break more evenly in February if treated thus. Much of the failure with these beautiful twining shrubs is due to lack of such treatment, and growing them under too heavy a shade.

Baskets of trailing plants that will be used for hanging on verandas next Summer may be filled in January. Trailing Queen Fuchsias are useful for this purpose. Pinch out the hearts of the shoots until eight weeks before they are wanted to flower. Ivy leaved geraniums are also useful for this purpose but should not be mixed, each variety should be in a separate basket. Another at-

tractive plant for hanging baskets is *Abutilon megapota-micum*, synonymous with *Abutilon vexillarium*. *Othonna crassifolia*, a plant now seldom seen, we have also used for basket work, and perhaps one of the most beautiful is *Lantana sellowiana*, synonymous with *L. delicatissima*.

The Gardenia house at this season needs to be carefully watered and syringed, taking care that the foliage is dry by sundown. Rain water is by far the best for them, and it is well to have it at the same temperature as the house they are grown in, which should be close to sixty-five degrees at night. If they are bench worn, the bench should be well filled with roots to secure flowers at this season of the year.

Poinsettias will be at their height at Christmas; these plants develop their bracts best in a temperature of not less than sixty degrees at night, and all draughts must be avoided. A door carelessly left open, causing a chill, will be sure to result in a loss of foliage. We have found that this *Euphorbia*, and the variety of *Jacquiniaeflora*, are very resentful to sudden changes in the temperature as Fall approaches.

Lapageria alba and *rosea* deserve a place in all private greenhouse collections. I know of no other plant whose sprays lend themselves so well for mantel decoration, if used with *Adiantum* ferns, especially the variety *Farleyense*. The coldest greenhouse is the place to grow them successfully.

If *Eucharis amazonica* has been kept on the dry side about a month before Christmas, a crop of flowers may be expected then. This plant should never be kept in a temperature of less than sixty degrees. Planted out on a bench it enjoys bottom heat.

Sow annuals for Spring flowering, which will fill any vacancies that may occur in the greenhouse in Winter.

A batch of the earliest ripened *Gloxinias* may be started now. They like a good open leafy soil, and a temperature of not less than sixty degrees while they are growing, also grow them well up to the glass and slightly shaded from the strong sun.

Keep the *Schizanthus* close to the glass in the coolest house, shift them before they become pot bound. Large plants, say in nine-inch pots, may be pinched four times before they are allowed to run to flower.

Calanthes as they pass out of flower must be allowed to dry out. They may be taken out of the pots and set on a dry shelf. *Calanthe veitchii* and *sandhurstiana* are among the best of our Christmas flowers and form a charming decoration when arranged with various forms of the maidenhair ferns.

Dendrobium nobile, *D. wardianum*, *D. thyrsoflorum*, are resting. Give them a good drying out until they set their flower buds. The temperature of the house should be around fifty degrees by night. As soon as the flower buds set, dip them in rain water, giving them a good soaking. If they are a little bit shrivelled, they will soon plump up. *Dendrobium phalaenopsis schroederianum* may be kept on the dry side until the young growths are an inch long, as these are liable to damp off, especially if watered with chilled water. *Oncidium splendidum* is throwing up its flower spikes and should be watered well with warm water of about the temperature of the house they are growing in. Weak liquid manure may be given them right up to the time they open their flowers.

Laelia anceps is again beginning to flower. The general complaint is that this orchid is useless as a cut flower but if the stems are scraped a few inches up, they will take water more easily; also split the stem a few inches and use quite warm water, letting them stand in a tight closet over night.

There are now many fine forms of *Cypripediums*. They also enjoy weak manure water when in good health, after

the young growths are well advanced and right up to the time of flowering.

Those that have to force very early grapes may start a house of Black Hamburg by the first of January. After all the many varieties that have been tried for forcing, this grand old variety still stands supreme as an early forcer, and is still one of the best flavored grapes we have. Remove all the loose soil on the top of the border and apply any fertilizer that has been tried and found to produce a good well flavored crop. So far, we have found bone meal, lime, Thomson's vine manure, and Clay's fertilizer very good, and of course, after the vines are growing good and have set their fruit, liberal applications of cow manure water. After the fertilizer has been applied, it may be covered with a light coating of good fibery upland loam. A good watering may also be given, but in an early grapehouse the water ought at all times be at least the same temperature as the border. Start the vines in a temperature around forty-six degrees and about every ten days increase it five degrees at night and ten during the day, gradually working up to sixty-five at night and eighty during the day. Any later grapehouses, if the vines are old and the soil looks spent, may be greatly helped if the roots are gradually and carefully uncovered, shaking the old soil out of them, removing it and replacing with fresh sod. At the same time the roots may be raised nearer the surface, covering them with about four inches of good sod. Of course, we all know the best way to renew with young vines, but I have seen wonders with very old vines treated in this manner, at the same time gradually renewing the fruiting canes.

Pot vines can also be had in fruit very early in the season, if started now, and also peaches and nectarines if houses suitable to their growth are available. Peaches and nectarines require a temperature five degrees lower than grapes.

Strawberries that have been treated properly may be brought into a carnation house temperature. Apples and pears that are well established in their pots may be forced similar to nectarines. Remember that pot fruit needs to be carefully watched as regards watering as they dry out quickly and they need to be fed very liberally.

A good collection of books pertaining to gardening is necessary to any gardener who desires to be successful in his profession, for no matter how good a brain one may be gifted with, he cannot carry all the information necessary to his calling under his hat. There is never a day but what it is needful to look up something pertaining to gardening.

THINGS AND THOUGHTS OF THE GARDEN

(Continued from page 294)

Washington or Baltimore may be valueless even in Philadelphia, and I know that varieties which do finely near New York and in New Jersey are not successes in Massachusetts. What we need for outdoor culture in lieu of named sorts is an early flowering strain, seeds of which can be sown by an amateur and raised as easily as asters or marigolds, and which when planted out in a row in the "cutting garden" can be depended upon to give a fine autumnal crop of flowers. The time is near when we will have these strains offered; they will not displace named varieties but will popularize chrysanthemums tremendously among amateurs. I look to see the time when seeds of early bloomers will be offered in separate colors, although mixtures with their infinite variety of forms and colors will continue to appeal to many.

* * *

The cultivation of our native orchids is but little un-

derstood and it is tolerably safe to say that the bulk of plants collected or bought fail to survive over two seasons. They are not plants for culture in the garden proper but for naturalizing in the wild garden, or in suitable locations in the rock garden they are splendid. The *Cypripediums* as the largest and most showy of the family will naturally appeal to amateurs the most. For their successful culture it is very necessary to provide them with soil such as they have been growing in, and necessary to provide them with soil such as they have been growing in, and necessary shade. I have had good success with the noble *C. spectabile* naturalized, also with *C. pubescens* and *C. parviflorum*, each of which did better than the common *C. acaule*. The latter we often find growing luxuriantly below pine trees where there is a thick bed of decaying pine needles, in which very few plants seem to thrive, but even the addition of plenty of pine needles to the soil and a generous mulch of the same has for some reason failed to suit this plant. The other *Cypripediums* named are much less finicky and in a mixture of loam, leaf mold, and sand do very well. Among our hundreds of warm house *cypripediums* there is no variety today so stately and beautiful as a well grown *C. spectabile*.

* * *

I do not know whether or not the outdoor culture of any of our greenhouse *Cypripediums* has been attempted in the frostless section of southern Florida. There ought to be some varieties which should thrive outdoors there if given a suitable soil and location. It is a fact that not a few amateurs are successful in growing such orchids as *Dendrobium nobile*, various *Cypripediums*, and some *Laelias* and *Cattleyas* in their homes here, and it is surprising how well some of them flower. That some of these orchids are by no means tender is easily proved by the fact that *Odontoglossums*, *Masdevallias* and some other varieties which have been frozen in greenhouses during severe weather, when sprayed with cold water and allowed to thaw out in the dark, have suffered no apparent harm. Plants, frozen in express shipments, have also come out alright. This season I experimented with a small plant of *C. insigne* which had been growing outdoors all Summer to determine what amount of cold it would stand. Temperatures of 30° and 28° failed to harm it; when the thermometer fell to 26° a few leaves were slightly discolored, while a minimum of 24° finally killed it. It would seem that in the tropical region of Florida many of these plants and other tropical orchids should grow tolerably well. Also would it not be possible to sow seeds of such orchids as *cattleyas* and *dendrobiums* on mossy magnolia trunks and have them germinate? Surely these experiments are worthy of a trial, and open up alluring possibilities.

MINIATURE DAHLIAS

It would seem that European *Dahlia* growers are giving more attention to the raising of varieties suitable for garden decoration and cutting, than to the giant flowered exhibition forms. Dwarfness of habit, too, seems to be an important feature. Anyone who has seen the miniature flowered *Cactus* varieties with their dwarf habit and abundant blooming qualities, as well as the dwarf bedding singles of which *Coltness Gem* and the various *Mignon* varieties are examples, cannot help being impressed. Miniature *Peony* flowered forms are also in being, these apparently being a specialty of J. T. West, an English raiser, who has in the past, introduced many magnificent *Peony* flowered and other garden types of *Dahlias*.—*American Dahlia Society Bulletin*.

Notes From An Old Country Garden

ARTHUR T. JOHNSON, F. R. H. S.

IN both rock-garden and woodland at all seasons, save Winter, the Foam Flower (*Tiarella cordifolia*) is a delightful plant. At the time of writing (mid-November) its pretty foliage, which so tastefully adorns the stony clefts in the rock-garden and the margins of the wild garden paths, is still gay with the crimson and bronze of its autumnal coloring. Nor shall we have to wait very long before the Foam Flower begins to thrust up its flesh-pink, budding spires, for it is one of the earliest of Spring flowers to break into activity. As for the fluffy heads of blossom which last far into Summer, few flowers can create more pleasing effect in the half-shade with a background of green than these. But, being familiar to Americans as a native, one need not dwell further upon the charms of *T. cordifolia*. It has, however, a near relative in *T. unifoliata* (also American) which may not be so well known to my readers. This makes spikes of bloom three or four times as high and as large as those of *T. cordifolia*. Its broad, palmate leaves are some four inches across and they grow in a bold tuft and here have an inclination to remain green all Winter. *T. unifoliata* differs also from the above in one important particular, i. e., it never runs, but remains in one clump. It makes quite a good plant for the border where cool conditions can be provided and it is by no means averse to good living in the way of an occasional top-dressing of old cow manure.

Another little woodlander hailing from the New World which is very happy here is *Cornus canadensis*, the Bunch Berry, a creeping Dogwood of the Rockies and elsewhere. We have established this plant in one or two cool corners and, though not a showy subject, one's interest in it never seems to wane. In Spring and nearly all Summer it provides a succession of its creamy-white, four-pointed stars in their ruffles of green, and in the Fall the leaves develop rich shades of plum-red and maroon.

The Bunch Berry is associated in my memory of good days in many a forested defile of the Rockies with that daintiest of trailing plants, the Twin-flower (*Linnaea borealis*). Strictly speaking, I believe, *L. borealis* actually belongs to Northern Europe, the species (or form of the same thing) common to America and Canada being *L. canadensis*. At any rate, there is no doubt that the latter is much the finer of the two, being not only larger in all its parts, but the elegant, fragrant flowers, nodding on their hair-like stems, are a fuller-toned pink. In our gardens *L. canadensis* also has the reputation for being more easily established than the European form. We find but little difficulty in satisfying this delightful plant, all it seems to require being a half-shady nook with its roots in light vegetable soil and a mossy rock or stump to ramble over. The *Linnaeas* are allied to the Honeysuckle Family and their flowers have a faint odor of almonds.

To my mind one of the most attractive plants in bloom in our Autumn garden is the Winter-flowering Periwinkle (*Vinca difformis*). This has a habit and foliage somewhat after those of *V. major*, but it is not nearly so rampant a grower and in every way a much choicer species. *V. difformis* (*media*) comes from Portugal and the flowers it bears so liberally during spells of open weather from September to Spring are a cold, icy white with just a thin wash of palest blue to intensify their whiteness. These blossoms, with their sharply-pointed segments, are singularly lovely against the dark, glossy green of the foliage, and they are even more beautiful in shade, to which the plant is by no means averse. *V.*

acutiflora, though similar in all other respects, has its flowers tinged with pale lavender instead of blue. This is probably a geographical form of the above.

A Periwinkle that is entirely herbaceous may make an appeal to those who have to give all but the hardiest subjects a heavy Winter covering. I refer to *V. herbacea*, a pretty little trailing plant which throughout the Summer will adorn any sunny or half-shady ledge in the rock-garden with its long, prostrate branches and leathery, deep green leaves, and maintain a long succession of clear blue, star-like flowers. This appears to be quite hardy anywhere here in a well-drained soil. But as it propagates itself freely by rooting its creeping runners, small plants can always be lifted in the Fall, given Winter protection and put out again in Spring.

Though one of the first shrubs to assume its autumnal coloring *Azalea pontica* (*Rhododendron flavum*) has been among the last to yield. Thus, for some ten weeks the groups of this fine old species have been flaming with brilliant shades of crimson and scarlet, orange-yellow and bronze. I often think we do not value this splendid subject as highly as we ought to do, for it has merits which should give it a place among the very best of its race. It is perfectly hardy, easily grown almost anywhere, it flowers profusely, the large yellow blossoms are deliciously scented and then, to wind-up, there are those gorgeous Fall tints to which I have alluded.

It is by no means uncommon for *A. pontica* to attain the height of 10 feet and to have a diameter of equal dimensions. These old specimens may be rather smaller in the blossom than the younger ones, but when every twig terminates in a truss of flowers, the bush being lit from top to base with a flame of yellow, *A. pontica* can have few rivals, and the delightful fragrance of that mass of blossom will pervade the air of the whole garden. We find that this old favorite prospers and blooms well in very light, porous loam that burns hot in dry Summers, a feat that few of its kind can accomplish.

A little shrub that is always extremely attractive not only at this season but throughout the year is *Pernettya mucronata*. This is a dwarf evergreen from the Magellan Straits and it is probably the hardiest of all South American shrubs. It does not exceed much more than four feet in height with us, but it makes a dense thicket of growth with its thin, wiry stems and innumerable, small pointed leaves which are a very dark glossy green. *P. mucronata* belongs to the ericaceous family and if the little flowers that are produced in May are inconspicuous, the species makes amends for this short-coming by bearing a crop of berries of extraordinary size and in a wide variety of colors. These fruits ripen in early Fall and remain on the shrub until the following Spring—sometimes, indeed, until the succeeding crop appears. They are round, often one-half inch in diameter and afford almost every conceivable shade of color from white through blush to pink; from pink to lilac, purple and mauve and so on to rosy-crimson, blood-red and plum-black. Even little bushes of 6 inches in height are at the time of writing heavily clustered with fruit, and though so near the ground, birds and mice do not seem to touch their amazing yield.

These *Pernettyas*, distinguished by the color of the berries, are, as I have indicated, all varieties of the one species. They are hardy enough to stand 25 to 30 degrees

(Continued on page 302)

Bright Barked Shrubs and Trees, and Herbaceous Evergreen Plants for the Winter Garden

FLORUM AMATOR

BERRIED shrubs and trees are a large factor in a Winter garden, but shrubs with bright colored bark set among the former, and trees with bark in such colors set among the latter, and herbaceous evergreen plants set beneath these trees are the supplement of the berried plants and trees in such a garden.

In Winter the boles and branches of the trees, and the stems and twigs of the shrubs, since they then are devoid of foliage, stand out more prominently and the color of the bark is brighter than in any other season of the year. The small herbaceous evergreen plants, too, peeping through the leaves or snow give a ground finish, so to express it, to our Winter garden.

Green-barked shrubs are rare, but there is at least one, namely, *Kerria japonica*. This bright green-barked shrub is of a notably graceful form, and of low growth, and is admirably suited for planting between such red berry-bearing shrubs as *Berberis thunbergii*. Furthermore, it has the merit of being one of the prettiest shrubs in Summer as regards both flower and foliage.

The number of red-barked shrubs is larger than that of green. The brightest colored of all these, and the least seen, is *Cornus alba sibirica*, whose bark in mid-Winter is very notably red, especially when seen in sharp contrast with the snow-covered ground. There are two other varieties of red-barked *Cornus*, *C. sanguinea*, whose branches are red-barked in Winter, and stand out conspicuously, and *C. stolonifera*, whose slender branches are usually red, but not always, in Winter. The first two may be planted for contrast between black-berried shrubs, such as *Ligustrum vulgare* and *Rhodotypos kerrioides*. The graceful drooping branches of *Tamarix africana* also have a red bark, but this is not so pronouncedly red as that of the *Cornus*.

There are at least two well known yellow-barked shrubs, *Cornus flaviramea*, also called *aurea*, which has bright yellow bark, and *Forsythia fortunei*, which has bark of approximately the same color. Placed between either red or black-berried shrubs the yellow bark helps by contrast to bring out the color of the berries and vice versa.

The *Betula*, Birch, has several species and varieties with conspicuously white bark. We have *Betula alba*, European White Birch, and its several varieties, the bark of which is of a very pleasing silvery white; also *B. papyrifera*, Canoe or Paper Birch, and *B. populifolia*, the American White Birch.

Fagus americana or *ferruginea*, American Beech, has a handsome light gray bark, and *Platanus orientalis*, Oriental Plane, after the outer bark peels off in the Autumn has a beautiful and unique creamy white trunk and branches throughout the Winter season.

Several of the *Salix*, Willows, have yellow bark, *S. elegantissima*, Thurlow's Weeping Willow, has on its long, spreading and drooping branches a yellow bark spotted with brown. *S. vitellina*, Yellow Willow, has a yellow bark on its branches, and that of *S. vitellina aurea* is even more yellow than any of the other Willows. *Salix vitellina britenzis* has strikingly conspicuous bright red bark. There is at least one quite handsome tree, namely, *Tilia euchlora* (*dasystyla*) the Crimæan Linden,

whose young branches are covered with a bright green bark. It would seem as if Nature had reserved green almost exclusively as the color for the leaves of trees, shrubs, and herbaceous plants, and had been very negligently in her contribution of that color for bark and for flowers.

All of these trees should find a place in our Winter garden. The smaller trees with bright colored bark may be set to advantage between and on the same line with berry-bearing trees, and the larger between and somewhat back of the line.

First in this class come the hardy evergreen ferns, to which the partial shade afforded by the trees and shrubs in Winter and the heavier shade in the Summer, when the trees and shrubs are clothed with leaves, is grateful. In this category are our well known native ferns found in rich, and rocky woodlands over a wide extent of our country; *Asplenium marginalis* (*Aspidium marginale*) Evergreen wood fern, whose fronds are quite thick; *Asplenium Spinulosum* (*Aspidium spinulosum*) Shield Fern, whose fronds are finely dissected, and *Polystichum acrostichoides* (*Aspidium acrostichoides*) Christmas Fern, the best known of all, whose fronds are a shining dark green. These will soon become established in our garden.

Iberis sempervirens, Hardy Evergreen Candytuft, and its variety, Little Gem, and also *I. gibraltarica* should find a place in the foreground of our Winter garden, where it will flout old Hiems by blooming soon after he gets out of the gate, making way for Spring.

Vinca minor, Periwinkle, is admirable in a Winter garden; the thick leaves of the species are of a dark, shining green. This evergreen trailer, once established, will soon cover bare or strong places. There is a variety of *V. minor*, namely, *argentea*, whose foliage is splashed and marbled handsomely with gray and white and is known as the Silver Periwinkle, and another variety *aurea*, the Golden Variegated Periwinkle, whose leaves are variegated prettily with golden yellow.

There are a number of native plants, besides the ferns, which are evergreen and which should surely have a place in our Winter garden. Here *Epigæa repens*, Trailing Arbutus, one of the smallest, shyest, sweetest, and prettiest of all our wild flowers, with its neat evergreen foliage will thrive if anywhere in cultivation. Well under the shade of the trees we may plant the two *Pyrolas*, namely, *Pyrola elliptica*, shineleaf and *Pyrola rotundifolia*, the former found in rich woods from New England to Maryland, Iowa, Minnesota and northward, and the latter in damp sandy woods throughout the continent, south to Southern Georgia. The thick, shining leaves of *P. rotundifolia* resemble strongly those of *Galax*. Eligible also for our Winter garden are *Chimaphila* (which means Winter-loving) *umbellata*, commonly called Prince's Pine, and *Pipsissewa*, whose sharply serrate leaves are of a shining green, and *P. maculata*, whose common name is Spotted Wintergreen, because its leaves are variegated with white, but this is not to be confused with the true aromatic wintergreen. These two *Chimaphilæ* are found in dry woods, the former from Nova Scotia to Georgia and west to the Pacific, the latter from New England to Georgia and west to Minnesota and Mississippi.

How to Attract the Song Birds Around the Home

JOSEPH H. DODSON *

It is a comparatively easy matter to attract all of the song birds around your home on account of the trees, shrubs, flowers, gardens and grass, and the natural beauty of the grounds. Our song birds (insectivorous birds) are a real asset and should be protected from an economical standpoint, aside from their beauty and song.

Winter at "Bird Lodge." Note the Lod House in the Fore ground

as the natural protectors of our trees, shrubs, forests, gardens and greens from insect pests. The value of our song birds to man is based principally on their feeding habits. Their greatest help is through their activity in eating harmful insects, their eggs and larvæ. Without this constant aid we would be powerless to protect our trees and crops from the ravages of caterpillars, beetles,

Concrete Bird Bath

flies, gnats, etc., and with a colony of these wonderful birds you will not have a mosquito in your vicinity. And if there is anything in the bird world that represents home life, it is a colony of beautiful purple martins. Contentment, happiness, prosperity is here and the cheerful social twitter of the martins and their industrious habits are a continual sermon from the air to their brothers of the earth. So those who love the martin for his cheery social nature and his inestimable worth should do something at once to educate those who do not appreciate

So those who love the martin for his cheery social nature and his inestimable worth should do something at once to educate those who do not appreciate

Cement Bird Bath. Popular with Song Birds Because It Slants Gradually from Edge to Center

this valuable bird. Martins live in colonies and are encouraged by the placing of colony houses.

Our Agricultural Department reports that the loss to our crops, gardens, trees and shrubs from injurious insects in 1922 was \$1,400,000,000. (The codling moth and curculio apple pest cost us \$12,000,000 a year in the reduced value of the apple crop, and more than \$8,000,000 a year in the cost of spraying the trees to keep them from destroying even more.) The loss can be entirely eliminated if we increase the number of our song birds to what it was before the building of our great cities, and the denuding of our forests, which have taken away the birds' natural nesting sites. Even if a bird should find a hole in a tree suitable for a nesting site, the tree surgeon comes along and fills it with cement. He does good work by saving the trees, but the birds are left without

Table and Bird Bath

places to build nests. Therefore, it is necessary that we should furnish them with man-made houses and shelters in which to build their nests and raise their young, and with sheltered feeding stations where they can find food

and shelter in times of stress; these should be put out now. The feeding shelters should be kept stocked the year round so that the birds will know that they can always find the food they require, and shelter at a given place. I am satisfied that my great success in attracting the song birds around beautiful "Bird Lodge," my home on the Kankakee River, is due to the fact that our song birds know that they can always find food, shelter, and protection from their enemies at all times. I can actually predict the approach of a storm twenty-four hours in advance by the number of strange song birds that fly into our grounds for food and shelter.

Now, it stands to reason that a bird is going to build where it can find nesting material most easily; therefore, this should be furnished them. It consists of string and twine cut into six-inch lengths and old gunny or potato sacks cut into six-inch squares. This material should be fastened securely on the inside of the shelters so it will

*Completed Mud Nest in the
Shelter*

always be ready. The birds love to pull this out and weave it into their nests. It is also a good idea to tack these squares up in different places on the grounds out of sight of the human eye, but where the birds will readily find them. Pans of mud should be furnished for the birds that wish to cement their nests together. It is very interesting to watch them shove a piece of string down in the mud and then carry it to their nest and hold it in place until the mud sets. Many of our song birds such as the robin, cardinal, and rose-breasted grosbeak, cat-bird, and brown thrasher cement their nests together with mud.

Bird baths should be put out and supplied with fresh water, as nothing will attract the song birds to your grounds as much as a number of the right kind of bird baths, placed in different localities where the birds can always find water to drink and a place to bathe. They

prefer shallow drinking places and are afraid of large bodies of water, but when they become accustomed to seeking water in a given place, they will always go there. Another great attraction for the birds is the planting of trees and shrubs that will provide food in abundance for them and the planting of these beautiful trees and shrubs are really necessary to insure success. I have spent practically a lifetime in selecting and collecting these varieties, which are just as hardy and far more beautiful than

Purple Martin House at "Bird Lodge."

ordinary shrubs, as they have first the bud, then the flower, and then the fruit. There are so many varieties that they furnish a complete supply of food for the birds, practically the year round.

After attracting the many song birds to your grounds, protection from their enemies is absolutely necessary, chief of which are the cat, house sparrow (English sparrow), red squirrel, skunk, fox, crow, cooper and sharp shinned hawk. The cat is the worst enemy, and takes an awful toll from our song birds. It is a fact that every cat will catch at least fifty song birds a year. At our last census there were 185,000 farms in the state of Illinois and our census recorded the fact that every one of those farms support a cat; some of them have many. On one farm fourteen were counted. For the sake of argument let us admit that every farm in Illinois has a cat, allowing that the cat only catches fifty birds a year, which is conservative. This amounts to nearly ten million song birds caught in the State of Illinois alone, and this does not include cats in cities and towns. There are more cats in the eastern states than out here. This being the case, is it any wonder that our song birds are decreasing in number?

Robins are more easily killed than other birds because they trust us most. They seem to feel confident that their gratuitous work is so valuable, their song so sweet, and their love for everybody so deep that nobody would want to hurt them; then all of a sudden the cat's fierce teeth fang its breast, and the bird's surprise is boundless. With a look of conscious agony the bird seems to say, "If I must suffer this strange death, won't some one take my little ones this breakfast which I gathered for them

before I had eaten myself?" Shall we be chided for espousing the cause of that bird?

The house sparrow (English sparrow) is a terrible enemy of our song birds. It fights all of them, tears up their nests, breaks their eggs, and kills their young. Besides that, it is a pest; it is dirty, noisy and quarrelsome. I am satisfied that I never could have been as successful as I have been in attracting the song birds around my home, lovely "Bird Lodge," if I had not eliminated this "rat of the air," with my sparrow trap. J. Andre Mottu of Norfolk, Virginia, recently wrote me that he caught 11,241 sparrows with this trap. This is the record catch, although I have several friends who have caught from three to five thousand of these pesky little varmints through the use of my sparrow trap. The sparrow is a grain-eating bird and should be classed with the chicken. They are good to eat, tasting like squabs and there is no reason why we should not eat them. They have eaten sparrows in the old country for centuries. There are millions of them and everyone eats its weight in grain every day. Everything has its uses. Don't be prejudiced; the sparrow has been used for food in Europe for years and sold for seven cents apiece during the war. Sparrows in a pie have very often been mistaken for squabs.

There is no doubt, if facilities are provided, that you will be astonished at the number of beautiful song birds that can be attracted to your grounds, and the best part of it is, that many of them will stay with you all Winter. The cardinal grosbeak, for instance, will not migrate if it can find food and shelter. The birds that do migrate return to the same houses year after year and with their natural increase, your grounds will soon become a veritable bird paradise. Make friends with the native song birds. They richly repay for the trouble you take in looking out for their interests. Many who have only a little patch of city garden have induced song birds to live with them, through my advice. The birds make no distinction between the rich and the poor.

In connection with this article, illustrations are shown, how birds may be properly cared for. The houses should be left up the year round, as they furnish building sites in the Summer and shelter in the Winter. Many birds stay with us in the north all the year; others go south chiefly because they cannot find food and shelter during the Winter in the northern states. Many species will go, of course, for love of warmth and sunshine, but a good many birds can be kept north all Winter if they are provided with food and shelter. I have proven this after years of effort.

It has added a great deal to my pleasure to have the birds stay with me, some of them only a month or two longer than they used to stay, some of them all Winter long. Few people realize how many birds starve to death during the sudden cold snaps, particularly when the snow covers the ground. Well stocked food houses and sheltered feeding tables are life-saving stations. I wish all realized this; I know everyone would lend a hand in feeding birds and would teach the young folks to look out for feathered friends. It seems to me that boys and girls of our bustling times are not taught to be as thoughtful as we used to be. This is not a peevish cry of "Those were the good old days." I believe we are going to have still better days for our song birds, because the American people are becoming alive to the great need we have for our native birds and the wonderful service these birds give in protecting our trees, shrubs, grains and fruits from harmful insects.

My suet cake, made of suet, sunflower seed, my grain mixture, and ground nuts, grinding shell and all (they must have the shell for roughage), is the most attractive

and necessary food for the birds that stay all Winter, being a balanced ration which contains everything necessary to sustain bird life. The birds will require very little or no attention in the matter of food during the late Spring and Summer, but early in the Spring and in the Fall and Winter it is well to take care of them. My experience has proven to me that two feeding devices are better than one. The larger and stronger birds will invariably drive away the smaller and weaker ones, perhaps at the very time they really need food.

Purple martins, bluebirds, wrens, flickers, or gold-winged woodpeckers, white bellied or tree swallows, chickadees, nuthatches, and flycatchers are the most easily attracted to man-made houses. They are, also, among the most valuable, most sociable, and most delightful of all birds. There are dozens of other birds, however, which are won by setting out bird houses. Among the three or four hundred birds which live in my garden are robins, scarlet tanagers, orioles, cardinal grosbeaks (red birds), cat birds, brown thrashers, warblers, flickers, rose-breasted grosbeaks, humming birds, juncos, song sparrows, wood thrushes, vireos, cedar waxwings, downy and red-headed woodpeckers and many others. Some of these insist upon building their own nests; but they benefit by my bird baths, and build nests on my shelter shelves, or "invitations to nest," as I call them. They all know they are welcome. One song bird attracts another, knowing they are protected from their enemies.

I have always been interested in birds; even as a boy I built wren, martin and bluebird houses and studied their habits. Talk about the busy bee, it is not to be compared with a mother martin feeding her four young ones. It is amusing to see their mouths wide open. The mother starts feeding with number one and with careful rotation number two is fed next; then number three, and when number four's turn comes, its mouth is surely wide open. After it has been fed the mother will start all over again with number one, which by the way, is always the smallest and weakest bird. How do I know this? Because I watch them with powerful binoculars which bring them up so close that I can see their every move.

To win birds for the beauty and sweetness they add to our lives is really a great joy and one that renews itself each year; it becomes a source of greater and greater pleasure every year to live with the birds. I loved and worked for the birds for many years before I appreciated fully their value to the world as protectors, God-sent, against the devouring insects.

NOTES FROM AN OLD COUNTRY GARDEN

(Continued from page 298)

of frost and are not particular as to soil. It is said that they will even do with lime, an element to which most of their natural order object, and though they like sun they will put up with and berry freely in semi-shade. Propagation is easily affected by division, suckers, cuttings or seed. We use these shrubs as dwarf ornamental hedges, grouped in beds or about the margins of shrubberies or woodland paths and for forming a carpet, or undergrowth, for the taller brooms, laburnums, hawthorns and other flowering shrubs that are apt to get leggy.

If we read intelligently and seriously the signs of the times, we come to the conclusion that religion, not as mere profession, but as believed and practiced agreeably to the teachings of Him who spake as never man spake, is the supreme need of our generation. And it shall be true of every generation to "the last syllable of recorded time."—*The National Pictorial Monthly*.

The Gardener's Opportunity

M. C. EBEL

AT the annual Fall exhibition of the Horticultural Society of New York, and at some of the other Eastern shows there appeared in the list of successful prize winners a number of new names which have not heretofore been noticed as exhibitors.

Does this not indicate that the old time interest in flower shows is being revived and that the owners of country estates are again disposed to support flower shows as liberally as they did before the war caused a curtailment of expenses? I think so. I know of two instances where gardeners, only recently placed in charge of the estates but who quickly gained the confidence of their employers, sought their permission to exhibit at the Fall shows. Consent was granted, but with grave doubts that the gardeners could successfully compete against the regular exhibitors with such short preparation. The results proved otherwise, however, and I am now looking for great achievements at the International Flower Show next Spring from these two estates, although they have never exhibited before, as the owners have now become interested and their gardeners are quite enthusiastic.

There are many other employers like those just referred to, but there are also many gardeners who hesitate to approach their employers with suggestions or recommendations that might revive old or instill new interest. But why should they hesitate when the suggestions or recommendations they might make would be to the benefit of their employers? The employers cannot fathom what may be stored in their gardeners' minds that would tend to improve their estates.

No greater opportunities present themselves for the professional gardener to exploit his skill than the events that are to occur in the Spring of 1924—the International Flower Show at New York from March 17 to 22, the National Flower Show at Cleveland from March 29 to April 6, and the National Orchid Show at Boston in May. The time is none too soon to begin preparations.

These shows are as dependent for success on the small grower as they are on those who may compete in the larger classes, for it is the smaller classes for specimen plants and for one or two dozen cut blooms which help to make the shows interesting. The public enjoys studying the individual plants which is not always possible when the plants are gathered in a group of many varieties. As for Madame Estate Owner, she is gratified with her gardener's success when she observes her name in the press among the list of prize winners, and it does not really matter to her what the exhibit is, if it secures the honors.

It is at the flower shows that estate owners often begin to "sit up and take notice." They see the exhibits from neighboring estates and wonder why they cannot have the same high quality of flowers as their neighbors show. Then they begin to feel that while they are paying the bills, they are not obtaining the results. This is not always their gardeners' fault, for the disbursements are not always sufficient for the results they desire. But how are the employers to know this, if their gardeners do not intelligently inform them how much more could be accomplished in making the estate attractive through a little additional expenditure?

When a man is placed in charge of a business, he is expected to produce certain results, and if he cannot, it remains with him to make known the reason why. When a gardener finds that he is not producing satisfactory results, due to certain restrictions or limitations, in justice to himself he should inform his employer why the

results are unsatisfactory. In doing so, he may succeed in having the restrictions removed; at least he is performing his duty in informing his employer why the anticipated results are not forthcoming. There is no question but that the employers are demanding more and more that their gardeners possess initiative to recommend how an estate may be improved in order to provide more pleasure for its owner, and not merely be able to "keep a place up." They are looking for quality in their gardeners as well as the ability to work, and can see no reason why they should not have it. Sometimes it becomes necessary to explain that they are not paying the price of quality, but this is usually met with the response that they are willing to pay the price if they can obtain the quality.

This is no mere theory, but is based on what actually transpires in interviews with estate owners from all parts of the country who visit our offices. We are meeting with an entirely new class of owners of country estates, men still actively engaged in business who are acquiring estates somewhat as toys with which to play and for the sake of the joy they may derive from them.

The employers are manifesting much interest in the affairs of their gardeners through their support as sustaining members of the gardeners' national association, by the way they entertain them during its annual conventions, and in patronizing the association when knotty problems arise in connection with the management of their estates. It remains with the gardeners to continue to increase this prestige by showing that if given but half a chance, they are desirous and interested in minimizing the annoyances that estate owners have sometimes to contend with; for when all is said and done, it is really a fifty-fifty proposition.

Let us start now to do our share to make the big shows of the Spring of 1924 a tremendous success. Their success will arouse a greater interest in American horticulture and this spells greater opportunities for the professional gardeners. You, as a gardener, may not be in a position to prepare anything for the big classes, but you must be unusually handicapped if you have some glass and cannot grow a specimen plant—something not commonly grown—or a few dozen blooms to exhibit. It is far more creditable to be able to say when the shows are over, "I also ran," than to have to confess that you did not try at all.

There is nothing on earth today that will heal the jealousy and hatred that is permeating it, as will the love of flowers, for he who loves flowers, must love God, and he who truly loves God, cannot long hate his fellow men. So fellow gardeners, yours is a great mission through the ministry of flowers. Interest your employers in it. Approach them as friends, for if you have your employers' confidence, you will surely find that they are your friends and that they will give their co-operation and support to any good motive you may present to them. It is through better gardens and more flower shows that this gospel of the flowers can be spread.

The Golden Rule, correctly called also "The Rule of Christ," is, "All things whatsoever ye would that men should do to you, do ye even so to them." This is the absolutely perfect rule; therefore, nothing can surpass, equal, or eclipse it. If the human race would reduce to practice the Golden Rule for half a century, the brotherhood of man would be a living, breathing, blissful reality.—*The Herald, Washington, D. C.*

Collecting Orchids in Central and South America

(Continued from November issue)

INASMUCH as arrangements were now completed with reliable native collectors, I turned my attention to the business of collecting in the Andes around Bogota. In this region at an altitude of 9,000 feet, only terrestrial orchids are found. Some interesting genera, such as *Pleurothallus*, *Stellis*, and *Odontoglossum*, were very prevalent. The latter genus is notable for its yellow-flow-

Fig. 1. Upper Magdalena River on Raft en Route to the Navigable Port of Girardot.

ered species, *flavescens*, which is often mistaken for *Oncidium* when first seen. This species evidently will soon become extinct, since the natives collect the plants, strip off the leaves, and carry the pseudo-bulbs down to the market place where they are sold for food. We first discovered this species through the remains of the leaves which had been torn off and left on the trail. Another interesting orchid which is familiar in our collection is *Epidendrum*. The majority of the species are of epiphytic habit, but those in this region are terrestrial. They may be found growing either along the hedge-row in company with various other tall-growing plants, or in dense shade. The most common species noted is the pink-flowered *Epidendrum elongatum*.

"In addition to collecting orchids my attention was now turned to the collection of herbarium specimens. One of the most common plants here is the dandelion, which is of course imported with European or American grass seed. Drying specimens for the herbarium is not a very easy proposition in Bogota because of the moist atmosphere. After these daily trips all specimens had to be placed between drying pads and finally put in press to prevent spoiling. On an average it took ten days to two weeks to prepare specimens, all the drying papers being changed daily.

"A place of interest, both because of natural scenery and as a collecting area is Tequendama Falls. From Bogota, you can go by train to within three miles of the Falls and the remaining distance by ox-cart. The falls are not very large from the standpoint of volume of water, comparing them with Niagara, but they have a drop of over 300 metres. I think the natural scenery surrounding this area is the most picturesque I have ever

seen. For the Andes of Bogota, the hills are extremely rich in the orchids mentioned, and in general the flora is much richer. I was very highly interested in a white-flowered *Epidendrum* which I finally succeeded in reaching and bringing back for the Garden collection.

"On June 10 I was highly delighted to receive a telegram from the *Cattleya Trianae* collector at Natagaima, stating that the orchids would shortly be leaving that region and that the natives had brought in 50 arrobas more than he was supposed to purchase. My reply was that I would take all that had been collected.

"My next trip was to Girardot, the uppermost part of the Upper Magdalena River. Here I found fifty cases of the coveted *Cattleya Trianae* in the Norman Black warehouse awaiting my inspection. A half-dozen cases were unpacked, and I found that my instructions regarding packing had been carried out to the letter. The shipment was now ready for its homeward trip. The plants in this shipment were collected near the small village of Natagaima, where my native collector had his base of operations. From here he spread the news that he was in the market for 'Tulipans' and the natives immediately got together their pack-mules and started in all directions on the orchid hunt. After a period of three to four weeks the natives, with their pack-mules loaded with 'Tulipans' roughly tied in bundles, began to arrive. These were bought by the collector for so much the arroba. They were then cleaned and put under cover to dry, then packed in the cases without any packing material whatever. The most important feature was to see that the plants were absolutely dry when packed, otherwise they will rapidly begin to rot.

"The next lap of the journey was by mule back to

the Upper Magdalena River, twenty-five miles with two cases each being required. Here a large double-decked coffee raft was waiting. On this raft the cases were floated down the stream to my base of operations in Girardot. From there they were again freighted on mule back to the Norman Black warehouse, near by. The next part of the journey after their final inspection and O. K.

was in the hands of Norman Black. From the warehouse to the boat by pack-mule again, by steamer to Beltran, by train from Beltran to La Dorada where they were again unpacked and taken to a steamer on the Lower Magdalena River to continue their five or six hundred-mile trip to the coastal town of Barranquilla. From there they were sent by train to Puerto Colombia; from there by ocean steamer to Panama, where they waited to be transferred to a New Orleans steamer. At New Orleans they were taken in charge by our agents and shipped to East St. Louis by fast freight. To hasten delivery at the Garden, automo-

Crossing the Rio Vieja

bile trucks brought them to the Garden without awaiting transfer across the river by the Terminal Railroad. This itinerary of the orchids from their native environment to their new home emphasizes the fact that the biggest factor of expense is transportation and not the original cost of the orchids.

"After successfully getting the plants which I had been sent for, my thoughts now turned towards home. Unfortunately, most of the Magdalena ports were under quarantine for yellow fever which was prevalent in the Bucaramanga region, so I was advised to go by mule back over the mountains to the Pacific port of Buenaventura.

"Before leaving Girardot we bought medical supplies, etc. We went from here to Flanders and here caught a train to Ibague, the capital of the Departamento de Tolima. After locating the agent who furnishes mules for such trips we were informed that it would take nine mules and four horses to carry ourselves and freight, which included our trunks, two cases of orchids, an herbarium press, etc. To make the packs waterproof, everything had to be wrapped in American tar-paper and roped on the outside. We left Ibague at daybreak. My Spanish friend and myself were not expert horsemen. However, the Ecuadorean, who was brought up in the mountains of Ecuador, was qualified for the trip, and the Virginian had previously belonged to the United States cavalry, so he was likewise an experienced horseman. We had three expert guides, each carrying his famous machete about two feet long.

"Our first objective after leaving Ibague was Caja-Marca, where we arrived at dusk and managed to secure a shelter for the night. The next morning we were up again before daylight, our guides informing us that today's trip was the most dangerous of the four days, inas-

much as we would have to climb to an altitude of 10,000 or 11,000 feet by the Quindeo Pass. We were advised to ride mules for the day as they are very much surer-footed, this being essential in view of the narrowness of most of the trails. We rode mules for the first three hours and then changed to our horses, deciding that we would sooner take the chance than go further on mule back.

"The second day we were to make the town of Armenia, which was a hard day's ride, before dark. We eventually climbed to and were safely crossing the Quindeo Pass. The scenery throughout the day was indescribably beautiful. Crossing the Pass I noticed a large red fruit that looked like a strawberry. Stopping my mule, after a short climb, I found it to be a raspberry larger than the largest strawberry I had ever seen. My friends, who had not been so much interested in my orchid material, became alert at sight of this edible fruit. I found three ripe fruits and exclaimed 'This is the best find I have had yet; I will take the fruit home and try to introduce this large variety.' My friends replied: 'That sounds very nice, but we have allowed you to stop frequently for your blamed orchids and now that you have found something decent to eat you even want to take that away.' Three against one was too much for me, so the large-fruited raspberries were lost to science. I afterwards found that the natives called these 'moras.'

"After finishing our costly (to me) dessert we started to descend to Armenia which we could see in the distance but alas a few hours' hard ride away. The progress seemed to be somewhat slow so we spurred our horses ahead; otherwise we would have had to stay in the mountains for the night. Just before dusk, with the town in the distance, our leader said we would have to speed on to make the town. My horse evidently had usually led the pack-trains because he made speed only when in the lead, so we were placed at the head. We started down grade on a half-way decent road at full speed. The Virginian, who was bringing up the rear, and who carried a revolver, decided to pull off a little Wild West show by

On the Trail Tossard La Maria

the aid of his gun. The horses, evidently not used to such demonstrations, became somewhat frightened and increased their speed. This would have been to our liking had not my horse suddenly collapsed after one of these spurts. The only things I remember were flying hoofs and having the presence of mind to turn out of the way of the mule which was following. Before my friends could dismount I was up and helping the horse. The

Ecuadorian came up as white as a sheet and started feeling my legs and arms to see if any bones were broken. My friends said that my horse turned two somersaults and I turned three. It was evidently a lucky escape for me. If any bones had been broken it would have meant waiting for expert treatment until we reached the far-off town of Panama. However, I received nothing worse than abrasions on knee, hip and elbow. The horse could not be ridden the second day.

"We eventually arrived at Armenia without any further mishaps. After a hard day's ride over trails averaging four to six feet in width, with a drop of 7,000 feet on the side, we were ready for a good night's sleep.

"We again set forth in the morning. Inasmuch as my horse was lame, I mounted a mule for the day. Our objective for that night was La Maria. The scenery throughout the day was extremely interesting and I saw many orchids, both epiphytic and terrestrial. At noon we were approaching the River Vieja when our guides informed us that we would have to ferry across. The ferry turned out to be two hand-made canoes, about seventy-five feet long by three feet wide, tied abreast. These were attached by a ring to a cable stretched across the stream. As the canoes were poled along the ring slipped along the cable, thus keeping the ferry in a straight course. The river was about 150 feet wide and some thirty feet deep. It took about an hour and a half for the entire pack-train to cross, since all freight had to be unloaded from the mules and taken across separately, with the exception of the mule carrying mail, whose pack was left on his back. Most of the time was taken up in trying to force the mules to enter the canoes.

"After all were across and the mules repacked, we immediately started an ascent of several hundred feet, almost at a perpendicular. We passed some very interesting vegetation, especially *Lantana camara*, a variety of which is used extensively in our summer bedding. I also saw various species of begonias and araceous plants, such as *Anthuriums*, etc. Of particular interest was an entire hillside of tree ferns which were very tempting. However, the cost of transportation was prohibitive. We finally arrived at La Maria at dusk.

"We started on the fourth day's journey with Zarzal as our objective. During this day I was able to collect several epiphytic orchids which were brought back to the Garden. We reached Zarzal at noon and from here secured automobiles which brought us to Tulua at four o'clock. The next morning we left on the 'Ferrocarril del Pacifico,' or Pacific railroad, for Cali. We were advised not to leave Cali for the seaport of Buenaventura until our reservations for sailing were assured, because of the lack of good hotels in Buenaventura. So the Virginian and I, after two days in Cali, said goodbye to our friends and left by train over the mountains to Buenaventura. The scenery across the Western Andes is very picturesque. In spite of the fact that the journey is an all-day trip and very tiresome, it is extremely interesting for the botanist, observing the vegetation, varying according to the altitude." On nearing the Pacific coast one is particularly struck with the wonderful varieties of *Anthuriums*, *Philodendrons*, and ferns. We reached Buenaventura at five o'clock in the evening and sailed the next day, Monday, on the Panama-Pacific freighter, 'General O. H. Ernst,' for Panama, and arrived at Balboa early Wednesday morning.

"My first act was to locate C. W. Powell, whom I had previously cabled of my arrival. After leaving my baggage and plants in his care, I again boarded the steamer and took the trip through the Panama Canal.

On my return I was the guest of Mr. Powell for a week, during which time I went through his collection

of orchids thoroughly. On leaving, upwards of 200 plants were given me for the Garden, many of which are new to science and brought to this country for the first time. In exchange I presented Mr. Powell with one case of my Colombian orchids which I had brought with me.

"My next objective was the West Indies, and I arrived at Kingston, Jamaica, after a two days' trip. A week was spent in Kingston, the principal place of interest being the Hope Botanic Gardens. Through the courtesy of the Director I secured a shipment of large tree ferns, so necessary for our tropical fern house. These were obtained in the region of the Castleton Gardens, about fifteen miles from the Botanic Gardens. Various orchids and economic plants were also given me in exchange for a case of Colombian orchids which I had brought with me. I finally sailed for New York, bringing with me two crates of plants aggregating 900 pounds. On arriving at New York I was met by a special government representative. After various preliminaries, I finally placed the shipment in the hands of the American Express Company, thus terminating my responsibility for the expedition.

"My first communication from the Director notified me that the Colombian shipment had arrived in New Orleans. I immediately started for St. Louis and upon arrival found the imported orchids in every nook and corner of the houses, demanding immediate attention. Within the first month we had arranged in permanent baskets over 3,000 plants. Prompt action was necessary as the plants had come through in excellent condition and had started new growths which when developed produce the large mauve flowers. The sooner the plants could be permanently established in their baskets the more rapidly would the growths develop, with more chance of producing flowers at the scheduled time. The plants will undoubtedly produce their best display next year.

"The latter part of September twelve cases of *Cattleya Schroederæ* were received at the Garden. These were contracted for before I left Bogota. This is but half of the plants ordered of this variety and it remains to be seen whether any more will be shipped. Considering the length of time on the way the plants arrived in excellent condition."

AROMATIC CREEPING WINTERGREEN

ANOTHER candidate of good character for our gardens is *Gaultheria procumbens*, Aromatic Creeping Wintergreen, a plant on the border line between a shrub and a herbaceous plant. This plant, which has pretty evergreen leaves, is found in cool, damp woods, from Maine to Minnesota and Southward to Georgia, and also northward. In addition to the common name wintergreen it is called in the interior Tea-berry; in some sections also Box-berry, and eastward Checker-berry and Partridge-berry, the last two names being applied to *Mitchella repens*, also, and thus causing confusion. *Mitchella repens*, Partridge-berry, is a very pretty little trailing evergreen, herbaceous plant, the place of which no other plant can fill as well in our Winter garden. We should plant it about the foot of the trees just where it is most found in its native habitat in the dry woods from far north well toward the south. The ovate, shining leaves of this plant are often variegated with whitish lines. *Mitchella* belongs to the family Rubiaceæ, to which also belongs such important plants as the Coffee and Peruvian Bark trees, but *Epigæa repens*, the Pyrolas, and *Gaultheria* belong to Ericaceæ, the Heath family, which embraces so many of our native berry fruits and broad-leaved evergreens.

I will honor Christmas in my heart, and try to keep it all the year. — Dickens

Foreign Exchange Department

HYACINTHS IN POTS.—Select clean, healthy-looking bulbs, not large, but well ripened, heavy bulbs. It must be borne in mind that many varieties having small bulbs very often give the best spikes of bloom, and must not be discarded. Procure the bulbs early, and do not select from those exposed in shop windows or in open baskets, as this treatment sadly detracts from the value of the bulb. The best compost is well-seasoned turfy loam, well broken, but not sifted, and mixed with plenty of well-decayed manure and silver or river-sand. If this cannot be had, any good garden soil with plenty of well-decayed vegetable refuse or manure from an old hot-bed, to which add silver or road sand, will do. Avoid all soils that run together, for the more porous the soil the better will the bulbs succeed. If the compost is mixed together two months before it is used, it will be all the better. For general use 6-inch pots are the best. In potting place a large crock at the bottom for drainage, filling up the pot with the above compost. Clear the bulb of all offsets and loose pieces, and with the fingers make a hole in the soil, into which put the bulb, but do not press it in too much. Have previously prepared in the open air a level piece of ground with a hard bottom of coal-ashes to prevent worms getting into the pots. Place the pots on this and give the bulbs a good watering to settle the soil. After the surface has become fairly dry, cover the whole with fine ashes, old tan, sand, or leaf-mould to the depth of 6 inches. Let them remain thus for four to six weeks, so as to get the pots well filled with roots before the foliage starts into growth, as this is one of the most essential points. The time of potting should be regulated according to the use required, but a succession of bloom may be had from Christmas to the end of April by commencing about the second week in September, and potting some bulbs every fortnight up to the end of December. After the pots are removed from the ashes they should be cleaned from all impurities and gradually inured to light. Give them abundance of water, and keep as near the glass as possible. If not required early they may be placed on shelves in a cool greenhouse, in a frame, or on a window-sill, care being taken to protect them from frost.—*Gardening Illustrated*.

THE CREEPING ROSEMARY.—*Rosmarinus prostratus*, as the prostrate form of the common Rosemary is called, is a most delightful shrub for a dry wall, sunny ledge, or any other warm spot where the soil is light, and there is full exposure to the south or west. It is quite a fast grower, soon covering a considerable space with its pretty, arching branchlets, or closely hugging the rock face, and it flowers profusely. Here we can usually look forward to a good show of blossom in Autumn in addition to that of Spring, and the pale blue flowers are fully as large, if not often larger, than those of the type. The foliage of *R. prostratus* is a peculiarly fresh and glossy green, which looks well in the rock-garden at all seasons. Though not hardy, this variety will often survive an average Winter in places not noted for a mild climate, whilst in the south and west it is rarely affected. As a matter of fact the lowly, creeping habit of *R. prostratus* is distinctly in its favor in bleak districts, for not only is it thus less liable to injury by frost and cutting winds, but it may be much more easily protected than the ordinary Rosemary.—*Gardeners' Chronicle (British)*.

GREAT BELL-FLOWER, PLATYCODON GRANDIFLORUM AND ITS VAR. MARIESI.—Sometimes called the Balloon flower owing to the shape of the buds when on the point of bursting, this plant, allied to the Bell-flowers, is lovely. Groups of its delicately colored large flowers, borne in loose clusters at the extremity of the 18-inch high growths, are among the most beautiful things in the borders.

Of the palest mauve, with deep violet lines running down the inside of the flowers, it is a choice flower. It is a native of Siberia, and perfectly hardy, flourishing in any but a waterlogged soil; best of all in a friable, warm compost, where its fleshy root stocks may ramble freely. The handsome var. *Mariesi* comes from Japan, and is a much dwarfer plant, which flourishes under similar conditions. It has the most beautiful deep violet purple flowers, each 3 inches across.—*Gardening Illustrated*.

VIBURNUM CARLESH.—This beautiful *Viburnum* is a native of Corea and is quite hardy, and I know of no shrub that has such a delicious scent. It does not grow very tall, but spreads well and the foliage is broad and somewhat rough.

The waxy, white flowers are borne in a cluster at the top of the shoots, not unlike those of a white *Bouvardia*. The plant prefers a rich, moist soil and requires little or no pruning. It is a shrub that should be in every collection, however small, and is also suitable for growing in pots. This shrub flowers in April and will do equally well in sun or shade provided it has good soil to grow in.—*Gardeners' Chronicle (British)*.

CARYOPTERIS MASTACANTHUS.—This deciduous shrub from China is sometimes called the Blue Spiræa. It is of dwarf

habit, with silvery green foliage and blue flowers somewhat darker than those of *Ceanothus Gloire de Versailles*.

It is a splendid plant for a warm, sunny position, and flowers in September, which makes it especially valuable. The shoots should be pruned to two or three eyes during April and all weak wood taken out. The plant is apt to become overcrowded; therefore, to ensure fine, strong spikes of bloom the growths should be thinned when they commence to grow.—*Gardeners' Chronicle (British)*.

IRIS CRISTATA.—Few of the dwarf rhizomatous Irises are so delightful and satisfactory as *Iris Cristata*, from the mountains of Kentucky, Virginia and Carolina. Where it succeeds well, as it does in most places, it increases into a spreading mass of short, broad leaves and stems, four inches to six inches, or so, high, bearing wonderfully large flowers of a charming lilac or violet shade, decorated with a conspicuous crest, one of the features of the *Evansia* section, to which it belongs. It thrives specially well in some gardens and in these it is an object of great beauty.—*The Garden*.

IPOMÆA QUAMOCLIT.—Those who appreciate the Morning Glory family will find *I. Quamoclit*, with its finely cut foliage, one of the most interesting of them all. It is perhaps better when grown as a pot plant, being rather unreliable in the open in most districts. If the pots be limited in size—say, to 6 inches—very neat specimens may be grown, and a few spriggy branches inserted in the soil will keep the slender, twining branches in order. The blooms vary in color, but in most cases they are red, and consist of a long, slender tube with an expanded mouth, in the form of a star. *I. Quamoclit* is the Cypress Vine of American florists' catalogues.—*Gardening Illustrated*.

ABUTILON GOLDEN FLEECE.—Small pieces of *Abutilon Golden Fleece*, if plunged in their pots in vases, or in beds in the open, are very ornamental and flower quite freely. The variety is one of the showiest of the family, and when trained in the greenhouse and established in large pots, or when planted out, it blooms with the greatest freedom, and is well worthy of attention.—*Gardening Illustrated*.

YELLOW CROCUSES AND PHEASANTS.—Those who are purposing planting Crocuses in quantity in the grass will do well to be aware of the fact that many birds are specially partial to Yellow Crocuses and will frequently destroy the flowers. Pheasants are destructive both to the flowers and corms. It is rather singular that they leave the blue, white and striped varieties alone, while the yellow sorts may be entirely eradicated by these birds. I know of several places where Crocuses were planted in vast numbers in the grass. In these the yellows have gradually disappeared; while the blue, white, and striped sorts have increased very greatly. I have in mind a broad stretch of lawn in front of a large mansion where in Spring there are myriads of Crocuses of all colors except yellow, which were planted in the same proportion at the same time. It was found that the pheasants not only destroyed the flowers but pecked the corms away. As yellow Crocuses were desired these had to be planted in an enclosed garden where the pheasants scarcely ever entered, owing to the place being so much frequented.—*Gardeners' Chronicle (British)*.

CAMASSIAS.—These attractive and graceful North American bulbous plants are very valuable for June flowering. Although beautiful in the border while in flower, they are apt to become untidy afterwards, and the ideal place for them is a partially-shaded glade of the woodland, where they may remain undisturbed for years. *C. Cusicki* is a handsome species forming a rosette of broad, glaucous leaves, and throwing up tall, elegant spikes of large, pale lavender flowers with yellow anthers.

C. leichtlini produces tall spikes of starry, creamy-white flowers with pink anthers.

Two garden forms of *C. esculenta*, Royal Purple and Silver Queen, also produce handsome spikes of dark blue and light blue flowers respectively, and are well worth growing. When left in the same position for several years they should be given an annual top-dressing of rich compost, and as soon as signs of exhaustion appear they should be lifted and divided.—*Gardeners' Chronicle (British)*.

PHYSOSTEGIA.—This is a hardy herbaceous plant of perennial duration, and remarkably interesting on account of the peculiar sensitiveness of its flowers, which may at will be placed in almost any position by a move of the fingers at right angles, and will remain where placed for some short time. It was introduced during the 17th century, and is a native of North America. When exhibited at a recent meeting of the Royal Horticultural Society it was described as the "Obedient Flower," and created a large amount of interest and something of a sensation on account of this peculiar sensitiveness of the flowers.

The *Physostegias* are of the easiest culture, delighting in any moderately rich soil, and may be planted with good effect in almost any sunny position, producing numerous, well-branched, stout spikes of pretty, tubular flowers in clustered racemes, and arranged in the four directions of the compass.

The varieties are well worth growing, and merit the best positions in the flower border, being especially effective when planted in groups of three, six or nine in a clump, from July to September. *P. virginiana* has bright pink, tubular flowers, and grows three to four feet tall. *P. v. alba* has snow-white flowers, and grows only two feet tall. *Gardeners' Chronicle* (British).

MAGNOLIA STELLATA.—All the members of this family are fine, handsome subjects and the species under notice is no exception. It does not grow so tall as some, only reaching a height of four to six feet. It has small, waxy white flowers, and has the advantage of being very free flowering, which cannot be said of some other varieties. The tree flowers in March and April; the blooms are about four inches across and star-shaped. It forms a dense bush and the foliage is a beautiful light green. The flowers are sometimes marred by early spring frosts, but in an open season it is an object of great beauty. A bed of this Magnolia planted in a sheltered position is a fine sight when the trees are in full bloom, and the flowers are sweetly scented. This Magnolia is much used for pot cultivation; it is one of the best of shrubs for the front row of the shrubbery and should not be omitted when forming a new plantation of mixed shrubs.—*Gardeners' Chronicle* (British).

THE JUDAS TREE.—Of the small genus *Cercis*, this species (*C. siliquastrum*) is the most familiar, though it is by no means common in gardens. It is one of the oldest of exotic trees, having been introduced to this country from Southern Europe in 1596. The generic name appears to have been bestowed upon it by Theophrastus some two hundred years before the Christian Era, and tradition has it that it was upon a tree of this kind that Judas hanged himself. *C. siliquastrum* is generally seen as a low, somewhat spreading tree of fifteen to twenty feet in height, but it will attain a much greater height. It is a deciduous species, the broad, rounded leaves being a pale green changing to yellow in Autumn. The flowers, which appear before the leaves in Spring, are pea-shaped and are produced at the joints of the old wood, or even from the trunk. They vary a good deal in color, but in average specimens they are a full toned rosy lilac, so that a Judas Tree laden with these pretty blossoms on a sunny day in May is a very beautiful object. There is a variety with white flowers. Much of the beauty of the Judas Tree, however, lies in its characteristic habit of growth and equally remarkable bark. *C. siliquastrum* is naturally a sun-lover, and it will thrive in any well drained loam, the situation being one that is sheltered from cold spring winds and late frosts.—*The Garden*.

Brief Horticultural Jottings

According to the *Journal of the Royal Society of Arts*, swallows' nests are considered a great table delicacy by the Chinese, and a sumptuous Chinese dinner is not complete unless there is a dish of this palatable food. There are two kinds of nests, a white variety and a feathered variety, the latter having birds' feathers in the texture. The nests are obtained from the Malay Archipelago, including Borneo, Sumatra, Java, and the Philippine Islands. They are also found in other places, especially on the reefs or islets off the coast of Changpu. The popular belief that the nests are made from jellyfish or seaweed is said to be erroneous. The particular swallows' nests used are said to be rich in albuminous matter, the nitrogen content varying from 3.39 to 24.6 per cent.—*Gardeners' Chronicle* (British).

Dr. Sumner Coolidge, a relative of President Coolidge, has this season been thoroughly testing Dextrogerm, the new radio-active peat introduced by Bernard Field of Plymouth, Mass., and according to the *Boston Traveler*, the tests have conclusively proved that Dextrogerm, used on garden crops, will produce as good, and in many cases better, results than commercial fertilizers, at one-half the cost. The experiments were carried out on the understanding that the sanatorium should be at no expense unless the results were satisfactory. Alternate rows of corn and tomatoes were treated with fertilizer and Dextrogerm so that the subjects were under the same general conditions. While one or two crops were about even, many others showed a 10 to 20 per cent gain where Dextrogerm had been used. The experiments, we understand, were conducted under the direction of the State Department of Agriculture and will be continued next year on a 30-acre field.—*Exchange*.

Apples without cores or seeds are promised by a discovery announced at Abbotsford, Canada, the particulars of which have just been received by the Department of Commerce. According to the announcement a seedless and coreless variety of Fameuse apple has been developed, which differs but slightly in shape from an ordinary Fameuse by being longer and flatter at the ends, but with the typical coloring and flavor. Except for a slight marking

on the flesh which outlines the situation of the core in an ordinary apple, there are neither core nor seeds. The apples were developed in an orchard at Abbotsford, and the discovery that they were out of the ordinary was an accident. They had come from a new block of Fameuse, about eight years old, which had been top grafted on Rabka seedlings. The discovery was made while grading for market, but unfortunately no record was kept of the tree or trees producing the new fruit and it will not be before another harvest that steps can be taken for its development.—*American Fruitgrower*.

Comments from Our Readers

In the interesting note on Hibiscus in the November issue, "Florum Amator" states that "There are twenty-eight species of Hibiscus." This statement can hardly be accepted as completely inclusive. Bailey, in his *Cyclopedia of Horticulture*, notes that "there are from one hundred and fifty to two hundred species, but perhaps only twenty known horticulturally in this country." Over four hundred species are listed in the *Index Kewensis*, all in good standing from a botanical point of view, but probably not all grown under cultivation.

It is a genus which is pretty well spread over the earth; North and South America, China and Japan, South Africa, Australia, India, Abyssinia, and Madagascar. What a fine jaunt it would be to visit all the Hibiscus at home!

Besides the species mentioned by "Florum Amator" there are two others worth while growing as annuals just for garden display. *Hibiscus Manihot*, native of India, where it is perennial, makes a strong single stemmed plant six to eight feet high, with large palmately divided leaves. The flowers are pale yellow with a dark eye, and are six inches or more in diameter. If need be, the roots can be lifted and stored over the winter.

H. Trionum, a South African species, occasionally seen listed as *H. africanus*, makes a bushy plant about two feet high, with flowers also pale yellow with dark centre, about two inches across.—*H. E. Downer*.

Department of Book Reviews

STANDARDIZED PLANT NAMES is the title of an extraordinary volume just issued by the American Joint Committee on Horticultural Nomenclature. It is extraordinary because it is the first attempt in the history of horticulture to propose one scientific name and one common or vernacular name for each item in American horticultural commerce. It is extraordinary also because it includes, for the first time, the joint efforts toward this end of six important trade and semi-professional organizations and the eight strongest special flower organizations. Quite as unusual is the fact that this book has been the result of some eight years of effort by a subcommittee of eminent plantmen, which if charged for by these gentlemen would make the book cost double the price asked for it. These men are Frederick Law Olmsted, a distinguished landscape engineer, Frederick V. Coville, the Botanist of the United States Department of Agriculture, and Harlan P. Kelsey, well known as a landscape architect, plant expert and nurseryman. The work has also had the constant supervision of the Chairman of the American Joint Committee, J. Horace McFarland, who is likewise responsible for its peculiarly efficient and readable typographic form.

STANDARDIZED PLANT NAMES is a compact volume of 546 closely printed pages, including more than 40,000 entries in one carefully cross-indexed alphabetical sequence, with a type arrangement which makes the approved and unapproved names instantly and almost subconsciously appreciable. It has as well, in the only separated list, the official code and list of fruit names of the American Pomological Society. In this volume there has been no attempt to propose a new system of horticultural terminology. There has been a plain idea to "make buying easy" so far as commerce is concerned, and to make definite all transactions in plants and all literature about plants because but one name of its kind is used for each item.

It is only proper to add that a long and important list of collaborators has aided in getting together this tremendous collection of plant names, and in working over them for the end in mind. Dr. Bailey of Cornell, the various authorities of the Arnold Arboretum, experts in the Department of Agriculture at Washington, men acquainted with special plant groups all over the nation, have participated in preparing the copy and in reading the proofs. The book is consequently in no sense the expression of the terminological tendencies of a limited group, but a genuine endeavor to accomplish the object aimed at.

National Association Of Gardeners

Secretary's Office, 286 Fifth Ave., New York

The aims of the association are to elevate the profession of gardening by improving conditions within it.—To cement a closer bondship among all engaged in, and interested in, gardening—to create a greater confidence between employer and employee.

Co-operating with the Massachusetts Agricultural College, the association conducts a course in training young men for the profession, whereby they obtain theoretical knowledge as well as practical experience.

SERVICE DEPARTMENT

The National Association of Gardeners operates a Service Department to serve country estate owners in an advisory capacity in adjusting problems which occasionally arise in the maintenance of country estates.

Owners desiring the services of gardeners, thoroughly versed in all phases of the profession and qualified to assume the responsibilities the position calls for, as superintendent of a property, should apply to this department.

OFFICERS 1923

President JOHN BARNET, <i>Sewickley, Pa.</i>	Vice-President R. P. BRYDON, <i>Ohio</i>
Secretary M. C. EBEL, <i>New York, N. Y.</i>	Treasurer MONTAGUE FREE, <i>Brooklyn, N. Y.</i>

TRUSTEES (For 1923)—Thomas W. Head, D. L. Mackintosh, Arthur Smith, New Jersey; Robert Cameron, Massachusetts; Andrew L. Dorward, Rhode Island.

DIRECTORS—(To serve until 1924) William Hertrick, California; George H. Pring, Missouri; Robert Weeks, Ohio; Thomas Wilson, New York; Harold Bryant, Connecticut; Harry Cartwright, Michigan; H. Ernest Jowner, New York. (To serve until 1925) George Wilson, Illinois; James Stuart, New York; William Kleinheinz, Pennsylvania; Edwin Jenkins, Massachusetts; Carl N. Fohn, Colorado; Joseph Tansey, New York; John Tonkin, Pennsylvania. (To serve until 1926) Alexander Michie, New York; George F. Stewart, Massachusetts; Theodore Wirth, Minnesota; George W. Hess, District of Columbia; R. P. Brydon, Ohio; William C. Rust, Massachusetts; Charles Schroll, Wisconsin.

Moore. *Virginia*—Mrs. Arthur Lee. *Georgia*—Asa G. Candler, Jr., G. Gunby Jordan. *South Carolina*—Robert S. Mebane.

LOCAL BRANCHES

NEWPORT, R. I.: Andrew L. Dorward, chairman; Frederic Carter, secretary.
ST. LOUIS, MO.: George H. Pring, chairman; Hugo M. Schaff, secretary.
NASSAU COUNTY, L. I.: William Milstead, Glen Cove, chairman; James Kelly, Glen Cove, secretary.
BOSTON, MASS.: Andrew K. Rogers, Readville, chairman; James Donald, Hingham, secretary.
WESTERN PENNSYLVANIA: James Moore, Sewickley, chairman; Henry Goodband, Sewickley, secretary.
CLEVELAND, O.: Robert Weeks, chairman; Arthur Brown, secretary.
NORTH SHORE OF ILLINOIS: James A. Wilson, Lake Forest, chairman; John R. Clarke, Glenoco, secretary.
MONMOUTH & ELBERON, N. J.: Thomas W. Head, Red Bank, chairman; Frank T. Edington, Red Bank, secretary.
NORTH FLORIDA: Herbert Tickner, Orange Park, chairman; Alfred Addor, Jacksonville, secretary.

THE BOSTON BRANCH

A meeting of this branch was held at Horticultural Hall, Boston, on Friday evening, December 7. There was a splendid attendance at the meeting over which Robert Cameron presided. Andrew K. Rogers was elected chairman for the ensuing year and James Donald, secretary-treasurer. It was voted to hold quarterly meetings and to have a speaker on some live subject at each meeting. The question of the re-admission of delinquent members was thoroughly discussed; the meeting went on record as unanimously opposed to any letting down of the By-Laws for permitting suspended members coming back in the association without the payment of back dues, but felt that there might be occasional cases where the local branches and the national secretary could use their judgment. It was voted to send a letter of sympathy to Montague Free, sympathizing with him in his very heavy bereavement. Another meeting will be held near the date of the local conference which will take place during the great orchid show in May. Robert Cameron for over two hours kept the members interested in a word portrayal of his recent trip to Great Britain, describing many notable estates, parks, botanic gardens, and flower shows. He received an enthusiastic vote of thanks.

W. N. CRAIG, Secretary.

NEWPORT BRANCH

A meeting of this branch was held in Music Hall, Newport, on November 27. The plan of cooperation submitted by M. C. Ebel, national secretary, was thoroughly discussed and endorsed, all present agreeing that it would simplify matters considerably and bring the branches into closer contact with each other. Communications from the North Shore of Illinois and Western Pennsylvania branches were read, relative to the re-instatement of delinquent members and it was agreed that the By-Laws of the organization should be upheld, although it was suggested that some concession might be made to enable delinquent members to be re-instated on the payment of a specified sum that may be determined at the next meeting of the association.

FREDERIC CARTER, Secretary.

WESTERN PENNSYLVANIA BRANCH

A meeting of the members of the above branch was held in the Carnegie Library, Pittsburgh on Tuesday, November 20, James Moore, chairman, presiding.

Communications were read from a number of branches in reference to Article III Section I of the By-Laws. These were ordered placed on file. After a short business session the members enjoyed a sumptuous repast provided by the entertainment committee. It was decided to hold the next meeting on Tuesday, January 15, 1924.

HENRY GOODBAND, Secretary.

MONMOUTH AND ELBERON (N. J.) BRANCH

The November meeting of this branch was held on November 27 at the home of William Turner, Rumson, N. J.

A letter was read from the Western Pennsylvania Branch regarding Article III Section I of the By-Laws referring to members in arrears for dues. After a lengthy discussion, this branch went on record to abide by the By-Laws believing that to suspend them would be unjust to members in good standing, and liable to cause a bad precedent. However, this branch is ready at all times to do all in its power to advance the N. A. G. and the profession.

A letter was read from Mr. Ebel regarding communications between branches going through the Secretary's office, thus recording and holding on file such matters and relieving the local secretaries of much work. We heartily endorse this proposal and at the same time appreciate Mr. Ebel's splendid cooperation.

The subject of the sign nuisance was brought up. In this section our highways are being badly disfigured through this nuisance and a campaign is being organized to combat it with the help of our local societies.

The December meeting will be held at Elberon to accommodate our members living in that section.

FRANK EDINGTON, Secretary.

THE NORTH FLORIDA BRANCH

J. K. Brower, a member of this branch addressed the Florida State Florists' Convention on November 21 at Tampa, Fla. on the subject of "The Opportunities that Confront the Professional Gardener." This branch is taking an active part in the horticultural affairs of the state and will cooperate with other organizations in combating the bill board nuisance which is marring the scenic beauty of the highways.

NASSAU CO. L. I. BRANCH

The annual meeting of this branch was held on the afternoon of December 11 at the new country club, the Creek, Locust Valley, L. I., with Chairman James Duthie presiding. Communications from the North Shore of Illinois and Western Pennsylvania branches were read referring to a modification of the by-laws respecting the reinstatement of delinquent members, and after some discussion, it was voted unanimously as opposed to any change. A communication from Manus Curran, Sewickley, Pa., chairman of the committee appointed to investigate the desirability of having each branch recommend a director yearly, was favorably received, as was the plan submitted by M. C. Ebel, national secretary, to secure a more united cooperation between the branches. Mr. Ebel was made an honorary member of this branch.

The following officers were elected for the coming year: William Milstead, Glen Cove, chairman; James Kelly, Glen Cove, secretary; John McIntosh, Syosset, treasurer; James Duthie, Oyster Bay,—Alex Michie, Locust Valley,—Joseph Adler, Glen Cove, trustees. It was voted to hold meetings once a month, the next meeting to be held in Glen Cove January 9.

JOHN R. McCULLOCH,
Secretary.

AMONG THE GARDENERS

Anton Bauer for many years of Deal, N. J., and more recently of Tuxedo Park, N. Y., secured the position of superintendent to Mrs. W. L. Glatfelter, Spring Grove, Pa.

William Thomson secured the position of gardener to Mrs. A. C. Barnes, Washington, Conn.

Alexander Adams secured the position of head gardener under Richard Calvert, superintendent of Ormiston Gardens, the estate of J. E. Aldred, Glen Cove, L. I.

James Foulis secured the position of gardener to Clifton A. Crocker, Springfield, Mass.

E. S. Fletcher has accepted the position of gardener on the estate of D. Kelleher, Mt. Airy, Va.

MRS. MONTAGUE FREE

Friends of Montague Free, Horticulturist of Brooklyn Botanic Garden, and Treasurer of the National Association of Gardeners, were deeply grieved to learn of the death of his devoted wife which occurred on November 28th, six days after an operation. Those who knew her well realize what a great loss Mr. Free has sustained, for she was a helpmate and companion in the truest sense. Mrs. Free was blessed with a happy disposition; an intense love for plants and birds, and gifted also with artistic ability. Her skill in this direction had been recognized at the Brooklyn Botanic Garden, for which she had colored slides of plants and plantings. Though quiet and unassuming she will long be remembered and mourned by her many friends.

JOHN DAVEY

John Davey, founder of the Davey Tree Expert Company and the Davey Institute of Tree Surgery, who was widely known throughout the country as the "father of tree surgery," died suddenly at his home in Kent, Ohio, on the morning of November 8, in his seventy-seventh year. Mr. Davey was born in Somersetshire, England, and from his very early boyhood was compelled through circumstances to earn his living.

LUTTON QUALITY GREENHOUSES

Recommended by the Best Informed Gardeners

If it is a V-Bar greenhouse, it must be a Lutton, as the V-Bar construction is patented.

Lutton V-Bar Construction means—

Durability
Strength
Efficiency
Beauty

No Trouble—no repairs—no worry

Extremely easy to take care of. You are assured of **maximum production at minimum cost** of maintenance. The **scientific, efficient heating system** insures even temperature on coldest nights. There is extra high headroom, providing space for tall plants on side benches. **Perfect ventilation.** One of its exclusive features is its indestructible sanitary type of plant benches with galvanized iron frame, porous tile bottoms and slate retaining sides.

Write or call for further details, photos and evidence of superiority.

ASK A LUTTON OWNER

WM. H. LUTTON COMPANY

260 Kearney Avenue

Jersey City, N. J.

Not until he was twenty years of age did he find the opportunity to secure any education, but with the aid of the New Testament and a pocket dictionary, he taught himself to read. Continuing his self-education, he became in time a fluent writer and the author of several books on the care and protection of trees. Mr. Davey came to this country in 1873 and about forty years ago settled in Kent where the Davey Tree Expert Company was organized, which today is reported to employ over four hundred men and to carry on business amounting annually to a million dollars. Mr. Davey's ideas on the treatment of trees were not at first received with favor, but today they are accepted as the scientific method of the preservation of tree life. During the last few years, his oldest son, Martin L. Davey, who is at present a member of Congress of the 14th Ohio district, has directed the management of this

business. Commenting editorially on John Davey, the New York Evening Mail said: When John Davey died some days ago, comparatively few persons had heard his name. Yet, in the great cities at any rate, there are few who do not owe something to his life work. For it was John Davey who . . . perfected those methods of tree surgery that have done so much for city parks. The ancients believed that the spirits of the departed sometimes inhabited trees. We can believe that if John Davey's had that choice, it would choose a gallant oak for a dwelling place.

EDWARD F. REAGAN

Edward F. Reagan, for more than a quarter of a century prominent in gardening circles in Morris Co., N. J., died at his home in Long Branch, N. J., on December 5. He

had been in poor health for some time. Mr. Reagan was one of the charter members of the Morris County Gardeners' and Florists' Society and for twenty-one years, or until his removal from Morris Co. was secretary of this organization. Mr. Regan was born in Red Bank, N. J., about sixty-six years ago and after receiving his early education in the schools of that place, attended Rutgers College, taking a course in the botanical department. Some years later he moved to Morristown, N. J., and for thirty years was superintendent of the Louis Thebaud estate, retiring about two years ago. He is survived by his wife and daughter, Mary.

LOCAL SOCIETIES

NASSAU CO. HORT. SOCIETY

The assistant gardeners made a splendid showing at the meeting of this society for the Miss Alice De Lamar Special which brought out seven entries. President James Gladstone appointed Messrs. Churchill, Sutherland, Meech, Trepass, and William Milstead to judge the exhibits. Their decisions were as follows: three white chrysanthemums, first, Peter Smith; table decoration for assistant gardeners, first, Norman Bruce; second, James Young; third, Ernest Riddel; three fine plants of Begonia "Gloire de Lorraine," exhibited by James Kelly, were awarded a Cultural Certificate.

Frank Caphia of Roslyn was elected to active membership and four petitions for active membership were received.

A smoker will follow the annual meeting to be held on Dec. 12, at which time the election of officers for 1924 will take place. Exhibits for this meeting will be three cut poinsettias; 12 mixed carnations; 12 mixed roses. The meeting will start at 7 p. m.

ARTHUR COOK, Cor. Secy.

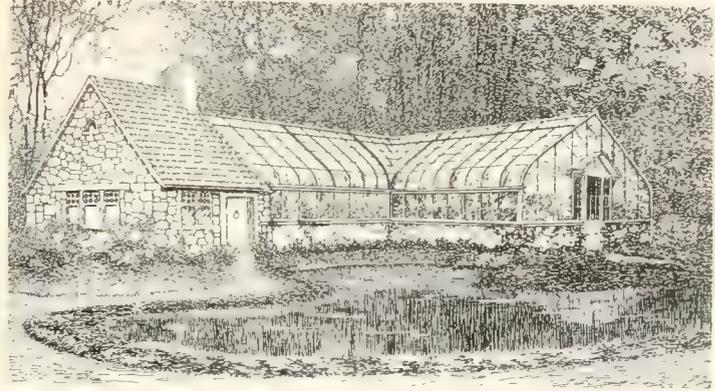

CLEVELAND HORT. SOCIETY

A special meeting was called for Nov. 12 at West Technical High School greenhouses, where this society was the guest of O. M. Eastman, supervisor of the Garden Department of Cleveland public schools, and A. S. Haag, instructor of Horticulture at West Technical High School. The school had a splendid exhibit of Chrysanthemums which had been on display to the public for three days; a few of the private gardeners had also staged some Chrysanthemums, Begonias, etc. There are one hundred and seventy-five pupils taking this course, and a great deal of credit is due to them and their instructor for everything in the greenhouses was in good shape. The Chrysanthemums were as good as could be found anywhere.

In the evening there was a meeting held in the class room, where Mr. Weeks, superintendent for G. Holden, spoke on Chrysanthemum culture, telling how Chrysanthemums are grown in England and how they are grown here. R. P. Brydon, superintendent for Mrs. F. F. Prentiss, spoke on Begonia culture, both the Lorraine type and the Winter blooming varieties. Mr. Scobi, a graduate of the horticultural course and now an employee there, spoke for the school. Mr. Jones, local chairman of the National Flower Show Committee, talked about the coming show, urging everyone to exhibit, large or small groups.

A rising vote of thanks was accorded the men responsible for the exhibit, and to the speakers. Refreshments were served by Mr. Eastman and Mr. Haag which ended an enjoyable and profitable evening.

This house with its attractive curved eaves and enduring steel frame was designed especially to fit a location, within a stone's throw from the residence

Greenhouse Convincement What, Therefore, Is It?

Always, in whatever you buy, there are two influencing factors. One—what the makers claim for the thing they make, the other—what the buyers of that thing, say. With most careful buyers, claims about what *can be done*, carry far less conviction, than evidence of what *has been done*.

If you are one of the latter, we have as conviction, greenhouses on the finest estates from Maine to California. Green-

houses, that were not merely built by us, but painstakingly designed to fit into the landscaping. They successfully combine the attractive with the thoroughly practical.

For considerably over half a century, we have been greenhouse specialists. Always, our Designing Department is at your disposal. To our printed matter you are most welcome. On your special request *only*, will a representative call.

How Constructed

All our four constructions have complete steel frames, either with or without metal mounted glazing bars.

1. Curved eaves with steel frame and cypress glazing bars.
2. Curved eaves with steel frame and galvanized steel U-Bar glazing bars.
3. Curved eaves, steel frame with galvanized steel V-Bar glazing bars.
4. Either number two or three with straight eaves.

WESTCHESTER AND FAIRFIELD HORT. SOCIETY

The regular monthly meeting of the above society was held in Greenwich, Conn., Tuesday evening, Nov. 13, with President Rutherford in the chair. Two new members were elected. As it is the wish of the society to have the annual dinner, the following were chosen as a committee to plan the entertainment, etc., for the affair: James Linane, James Tough and William Whitton.

The medals which were won at the recent Dahlia Show in Greenwich, were given out, the winners being: Mrs. F. Constable, Mamaroneck; Mrs. E. E. Smathers, Port Chester; Mrs. Whitelaw Reid, Purchase; J. H. Troy and Mills & Co., New Rochelle; Stump & Walter Co., New York; Walter Slade was awarded a Certificate of Merit for his vase of undissected Dahlias.

The nominations of officers for 1924 resulted as follows: President, Edwin Beckett and John Rutherford; vice-president, W. D. Robertson and H. F. Bulpitt; secretary, John Wilson and George Hewitt; treasurer, W. J. Sealey and James Stuart; corresponding secretary, William Whittan and Cyril Hayman; executive committee members: James McCarroll, Alex Marshall, J. McAllister, and James Linane.

The A. N. Pierson and J. H. Troy monthly competition awards were: 1st, Begonia, Edwin Beckett and also a cultural certificate for same; 2nd, W. D. Robertson, collection of Anemone Chrysanthemums; 3rd, Thomas Middleton, vase of Chrysanthemums; 4th John Wilson, Begonia. For vegetables, H. F. Bulpitt was first with a plate of apples; James Linane was second for six onions.

The committee had arranged a competition apart from the usual A. N. Pierson and J. H. Troy classes, the classes and winners were: Chrysanthemums; Class 1, twelve large blooms, first, James Stuart; Class 2, six large blooms, first, W. D. Robertson; Class 3, six vases of singles three sprays to a vase, first, Harry Jones; second, James Stuart; Class 4, six vases of Pompons, first, George Hewitt; Class 5, nine blooms of Anemone type, first, W. D. Robertson; Class 6, vase any varieties arranged for effect, first, W. D. Robertson; second, George Hewitt.

Vegetables; Class 7, collection of six varieties, first, Walter Slade; second, James Linane; Class 8, three heads of lettuce, first, W. D. Robertson; second, James Linane; Class 9, six leeks, first, James Linane; second, James Tough; Class 10, six onions, first, Walter Slade; second, John Wilson; Class 11, three cauliflowers, first, James Linane; Class 12, six celery, first, James Tough. George Hewitt received a certificate for a collection of pompon Chrysanthemums.

How Our Greenhouses Differ from Others

Outwardly our greenhouses are just like other greenhouses. But inwardly there's a great deal of difference.

Some owners have accused us of being rather fussy about our work, intimating that we made our corners and got the work done more quickly. And that was true. But you'll agree that we are also right in refusing to do it. That there must be certain characteristics in which our greenhouses differ. At your request we will gladly send you printed matter.

*The Insecticide that
 kills plant Lice
 of many species*

The Insecticide of Recognized Merit for Greenhouse and Garden

APHINE is a concentrated material—mixes readily in water—efficient in its action—easily applied—free of the disagreeable odors and features of most insecticides—excellent as a wash for decorative plants.

FOR THE GARDEN—As a remedy against all sap sucking insects infesting flowers, fruits and vegetables, APHINE is most effective.

FOR THE GREENHOUSE
 —Applied at regular intervals (once each week or ten days) APHINE will keep plants in the greenhouse and conservatory free of insect pests.

FUNGINE—For mildew, rust and other blights affecting flowers, fruits and vegetables.

VERMINE—For worms and insects infesting the soil.

The Tribute of Alexander J. Hans to Davey Tree Surgery

Locust Valley, Jan. 15, 1923

THE DAVEY TREE EXPERT COMPANY, KENT, OHIO.

Dear Sirs:

About a year ago your men treated some of the important trees on the Piping Rock Country Club grounds over which I have charge.

I inspected the work recently with your representative and found that in every case the sectional cement fillings are holding perfectly, and that the bark has healed over on to them from one-quarter to one-half inch.

The beneficial results of this kind of work are much more noticeable than when attempted by the average Estate men. In my opinion work of this character cannot be done by other than expert men who are trained in this particular line. Sincerely yours,

(Signed) ALEXANDER J. HANS, C. E., Superintendent

To save the old trees, every gardener and estate superintendent needs highly skilled assistance. Many, like Mr. Hans, protect their trees by Davey Tree Surgery—a science developed by a generation of study and experience. A careful examination of your trees will be made by appointment.

THE DAVEY TREE EXPERT CO., INC., 312 Elm Street, Kent, Ohio.

Branches in the following cities: New York, 1st, Trust Bldg., Fifth Ave. and 42nd St.; Boston, Massachusetts Trust Bldg.; Philadelphia, Land Title Bldg.; Baltimore, American Bldg.; Pittsburgh, 331 Fourth Ave.; Buffalo, 110 Franklin St.; Cleveland, Hippodrome Bldg.; Detroit, General Motors Bldg.; Cincinnati, Mercantile Library Bldg.; Chicago, Westminster Bldg.; St. Louis, Arcade Bldg.; Kansas City, Scarritt Bldg.; Los Angeles, Garland Bldg.; Montreal, 252 Languechitère, West.

Davey Tree Surgeons are near you—if you live between Boston and Kansas City, or in California. Write or wire nearest office for a list of locations of your trees without cost or obligation.
